

Blockchain DLOC Sem VII

NMCPC62 : Cryptocurrency and Blockchain Development

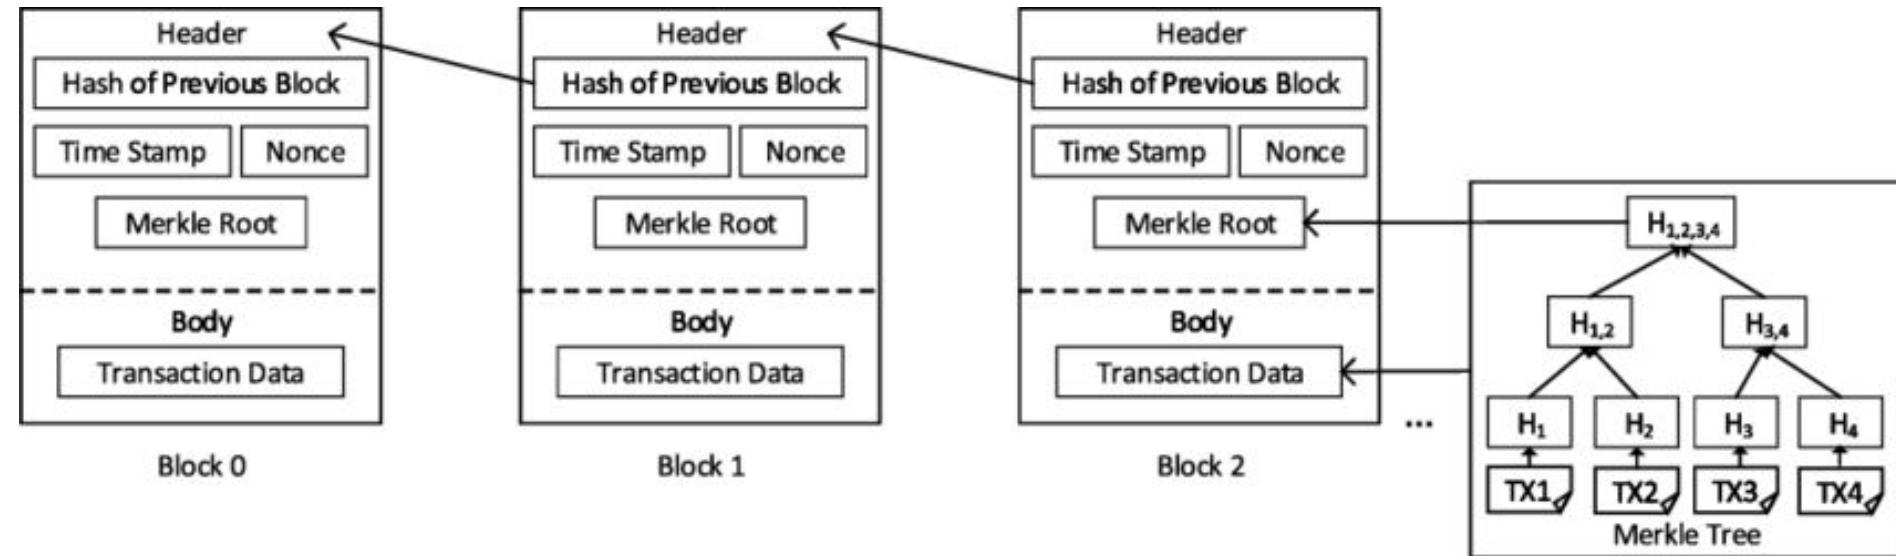

**Module - 2: Blockchain Architecture and Platforms
(6 Hours)**

Instructors : Geocey Shejy, Lifna C S, Pradnya Raut

Topics to be covered

1. Anatomy of a Blockchain:
 - o Blocks - Merkle Tree Root Hash,
 - o Transactions - UTXO, Transaction fees, How wallet works, SegWit,
 - o Nodes,
2. Types of Blockchains: Public, Private, Consortium, and Hybrid,
 - o Comparison, Technology Requirements
3. Exploring Key Blockchain Platforms:
 - o Bitcoin, Ethereum, Hyperledger, and Binance Smart Chain.
4. Smart Contracts:
 - o Concept, Structure, and Applications,
5. Overview of Decentralized Applications (DApps)
6. Token Standards (ERC-20, ERC-721, etc.),
7. Security Aspects of Blockchain: Attacks, Challenges, and Mitigation Techniques

1. Anatomy of a Blockchain - Block

1. Anatomy of a Blockchain - Block

Elements of a Block

- **Block Height –** It's the sequence number of the block in the chain of blocks. Block Height: 1 is the genesis block (first block in the network).
- **Block Size –** It's a 4-bytes or 32-bit field that contains the size of the block. It adds size in Bytes. Ex – Block Size: 216 Bytes.
- **Block Reward –** This field contains the amount awarded to the miner for adding a block of transactions.
- **Tx Count –** The transaction counter shows the number of transactions contained by the block. The field has a maximum size of 9 bytes.
- **Block Header –** The Block header is an 80-Byte field that contains the metadata – the data about the block.

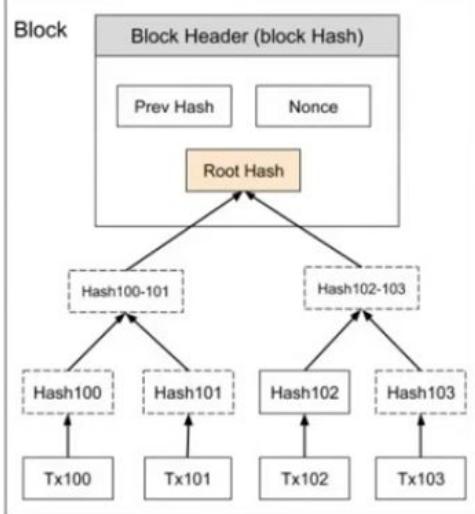

1. Anatomy of a Blockchain - Block

Components of the Block Header.

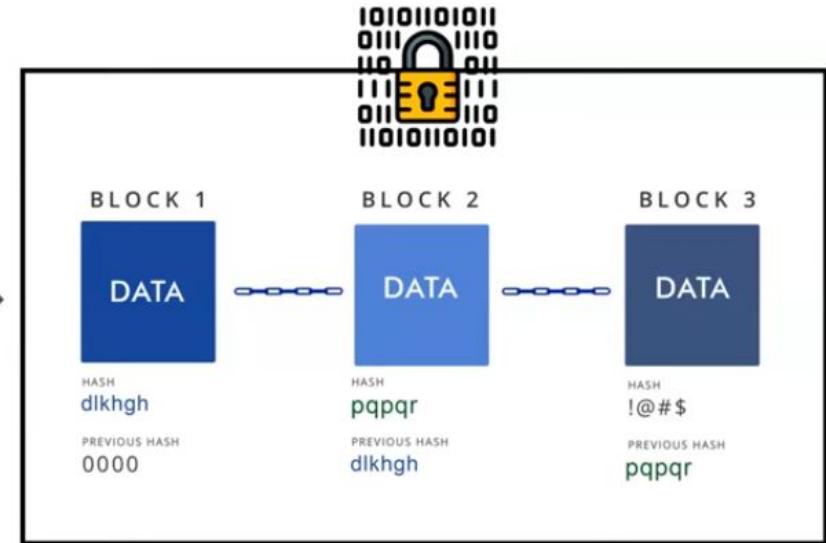

- **Time**
 - It's the digitally recorded moment of time when the block has been mined.
 - It is used to validate the transactions.
- **Version –**
 - It's a 4-bytes field representing the version number of the protocol used.
 - Usually, for bitcoin, it's '0x1'.
- **Previous Block Hash –**
 - It's a 32-bytes field that contains a 256-bits hash (created by SHA-256 cryptographic hashing) This helps to create a linear chain of blocks.
- **Bits –**
 - It's a 4-bytes field that tells the complexity to add the block.
 - It's also known as "difficulty bits." According to PoW, the block hash should be less than the difficulty level.
- **Nonce –**
 - It's a 4-bytes field that contains a 32-bit number. These are the only changeable element in a block of transactions. In PoW, miners alter nonce until they find the right block hash.
- **Merkle Root –**
 - A 32-bytes field containing a 256-bit root hash.
 - It's constructed hierarchically combining hashes of the individual transactions in a block.

1. Anatomy of a Blockchain - Block (Merkle Tree)

Merkle trees are a type of data structure commonly used in computer science. They are used to encrypt blockchain data more effectively and securely in bitcoin and other cryptocurrencies.

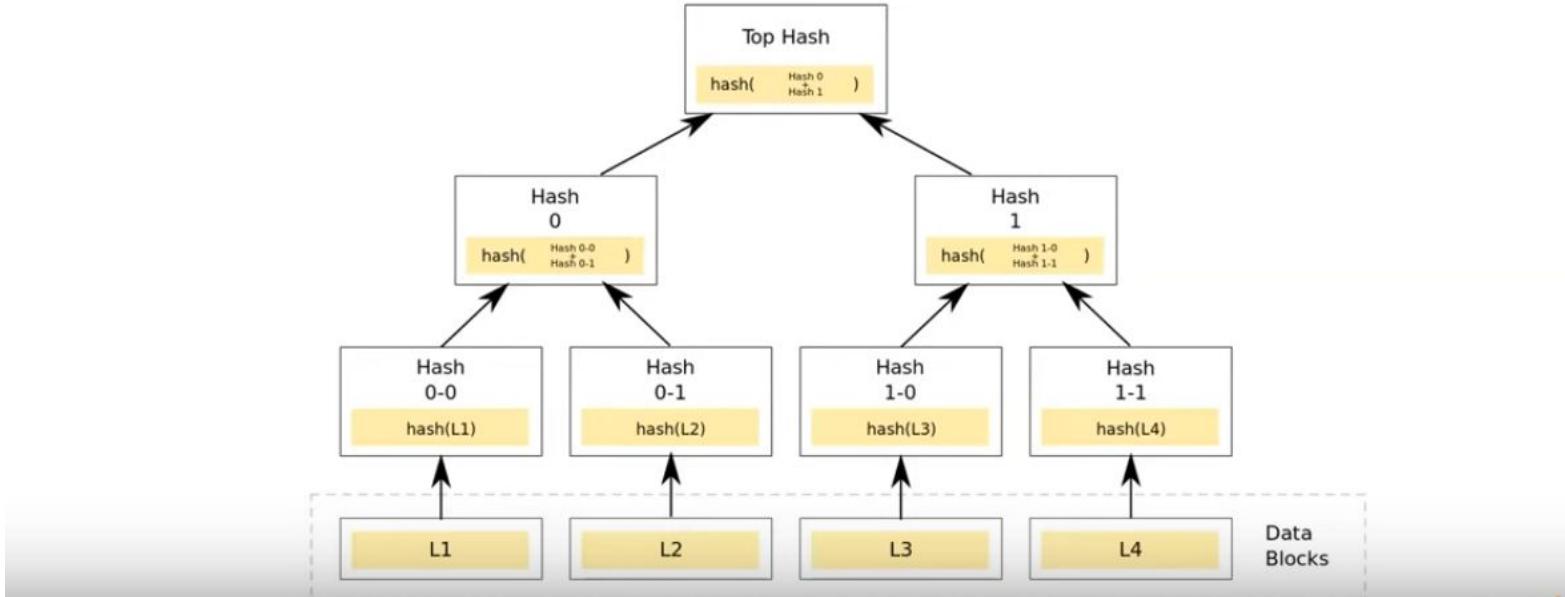

Merkle Tree

Blockchain Data encrypted Securely

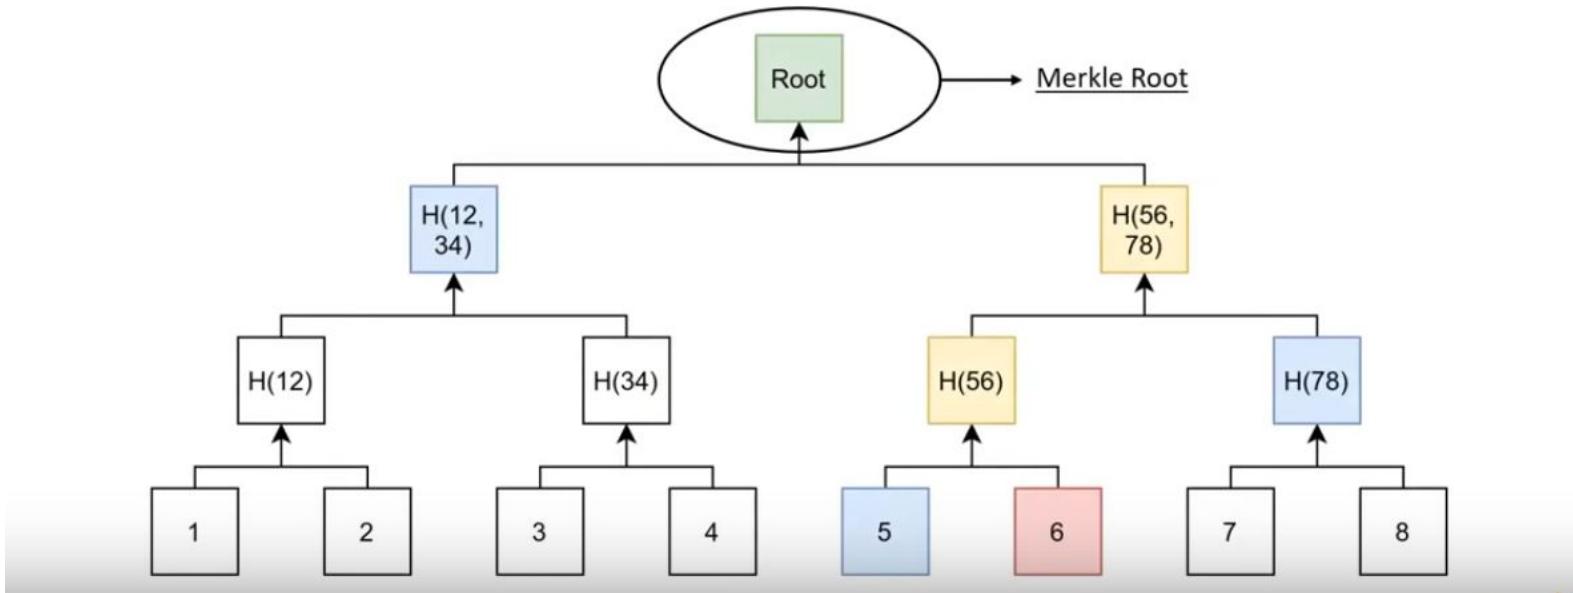

1. Anatomy of a Blockchain - Block (Merkle Tree)

It's a mathematical data structure or a method of organizing data, made up of hash number of various data blocks of transactions performed of the Blockchain Network. It acts as a summary of all the transactions.

1. Anatomy of a Blockchain - Block (Merkle Tree)

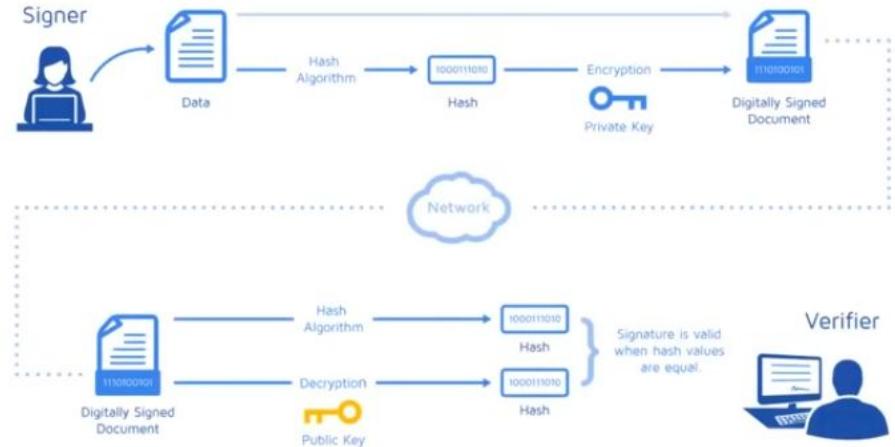

Merkle root is a simple mathematical method for confirming the facts on a Merkle tree. They're used in cryptocurrency to ensure that data blocks sent through a peer-to-peer network are secure.

1. Anatomy of a Blockchain - Block (Merkle Tree)

How does a Merkle Tree work ?

A Merkle tree totals all transactions in a block and generates a digital fingerprint of the entire set of operations, allowing the user to verify whether a transaction is included in the block.

1. Anatomy of a Blockchain - Block (Merkle Tree)

How does a Merkle Tree work ?

They're built from the bottom, using Transaction IDs, which are hashes of individual transactions. Consider the following scenario: A, B, C, and D are four transactions, all executed on the same block.

Transaction ID A

Transaction ID B

Transaction ID C

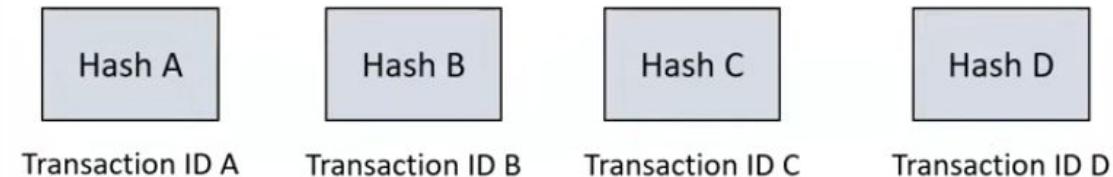

Transaction ID D

1. Anatomy of a Blockchain - Block (Merkle Tree)

How does a Merkle Tree work ?

Each transaction is then hashed, leaving us with:

Hash A
Hash B
Hash C
Hash D

1. Anatomy of a Blockchain - Block (Merkle Tree)

How does a Merkle Tree work ?

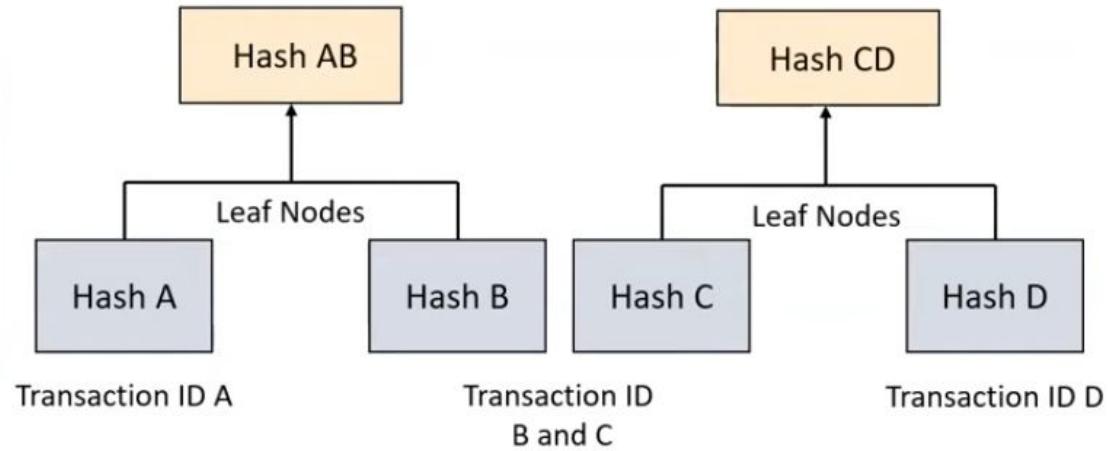

The hashes are paired together resulting in:

Hash AB

and

Hash CD

Our Merkle Root is formed by combining these two hashes: Hash ABCD.

1. Anatomy of a Blockchain - Block (Merkle Tree)

How does a Merkle Tree work ?

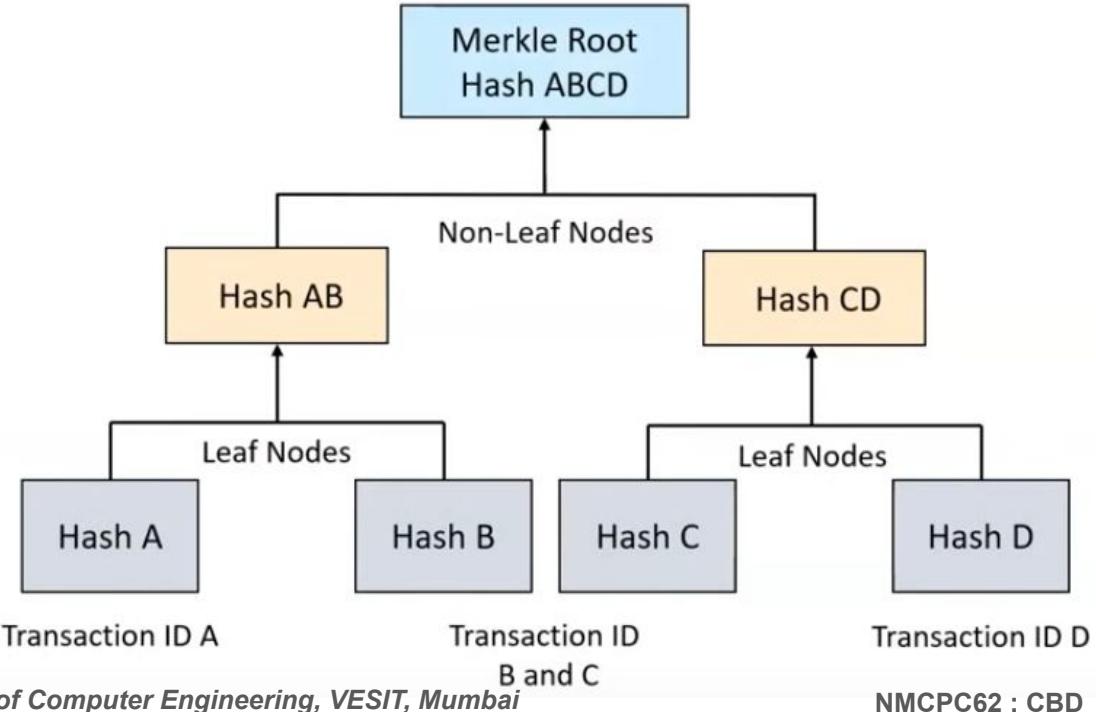

The hashes are paired together resulting in:

Hash AB

and

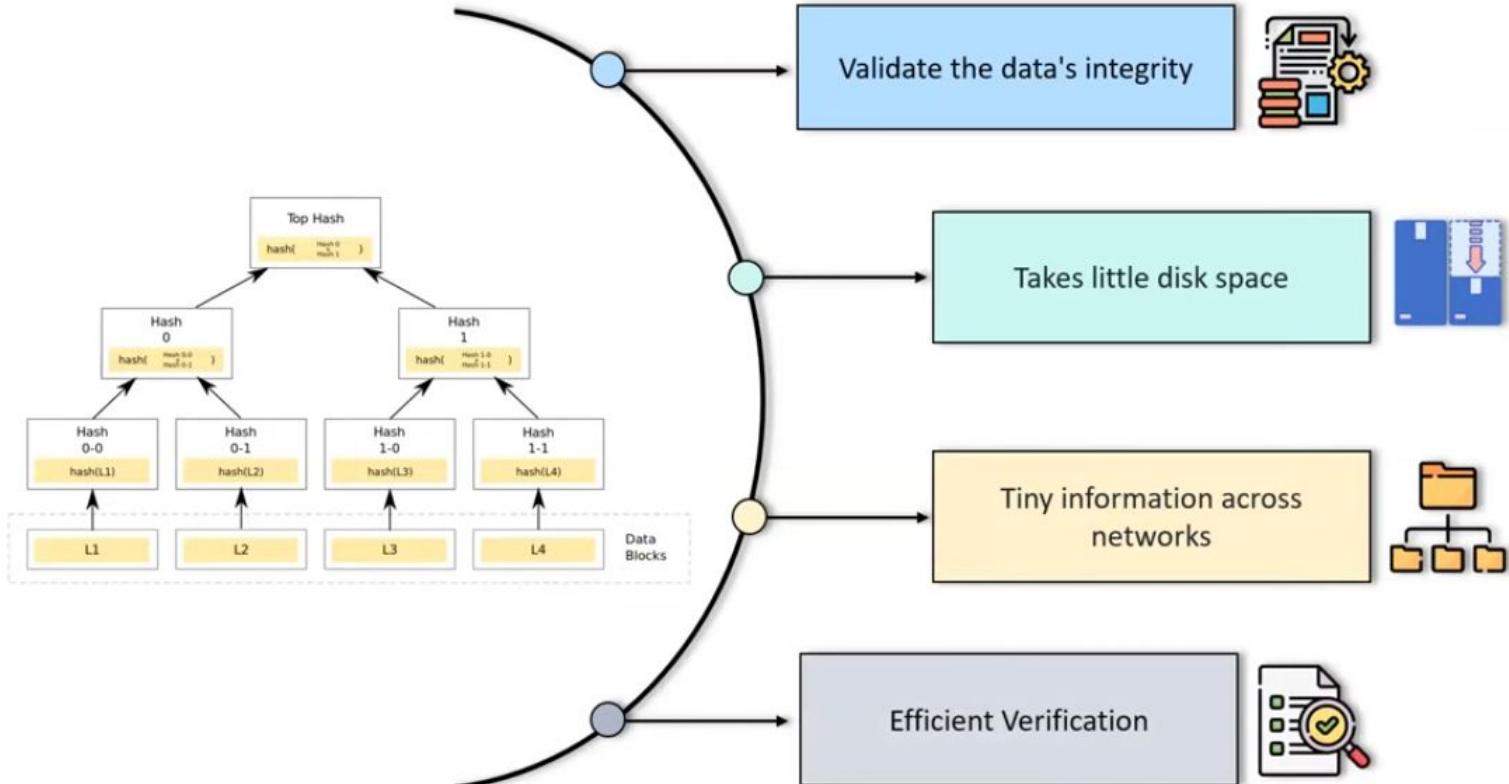

Hash CD

Our Merkle Root is formed by combining these two hashes: Hash ABCD.

1. Anatomy of a Blockchain - Block (Merkle Tree)

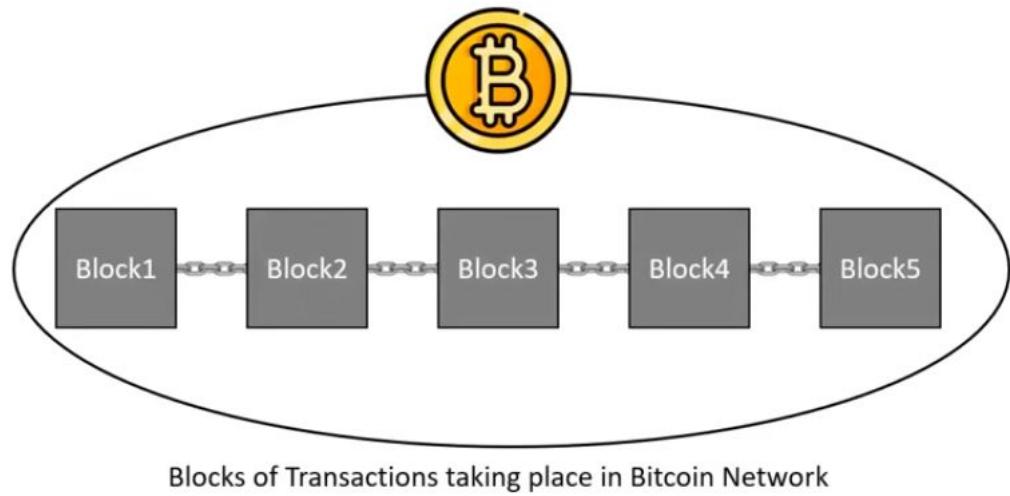

Benefits of Merkle Tree

1. Anatomy of a Blockchain - Block (Merkle Tree)

Why is it essential for Blockchain ?

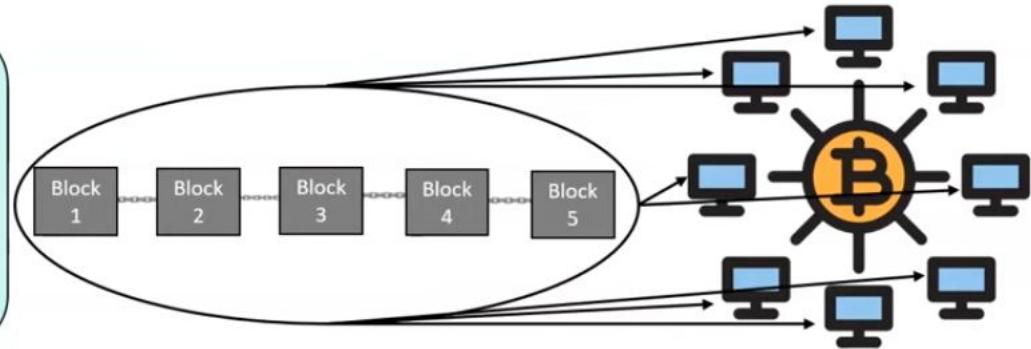

Let's imagine a blockchain without Merkle Trees to get a sense of how vital they are for blockchain technology.

1. Anatomy of a Blockchain - Block (Merkle Tree)

Why is it essential for Blockchain ?

If Bitcoin didn't include Merkle Trees, for example, every node on the network would have to retain a complete copy of every single Bitcoin transaction ever made.

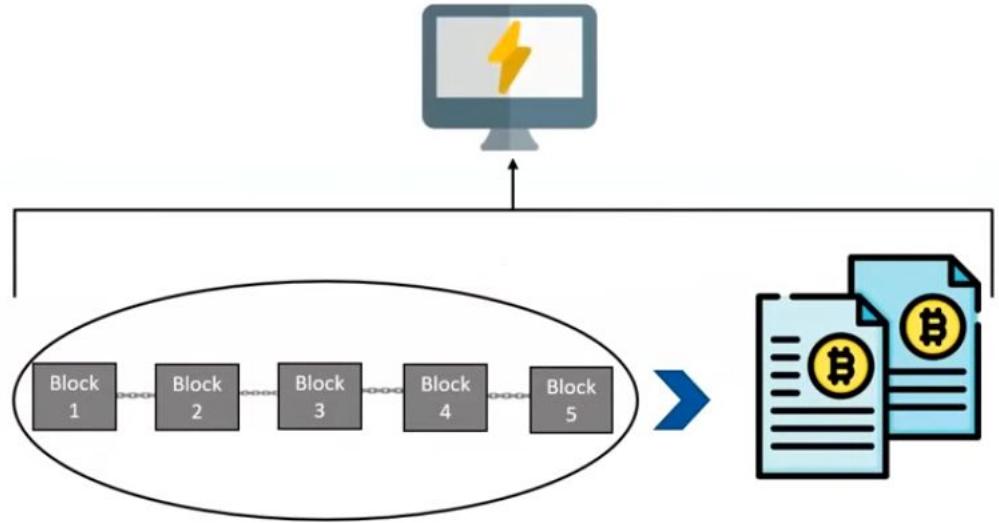

Too much information for every node to validate on their own

1. Anatomy of a Blockchain - Block (Merkle Tree)

Why is it essential for Blockchain ?

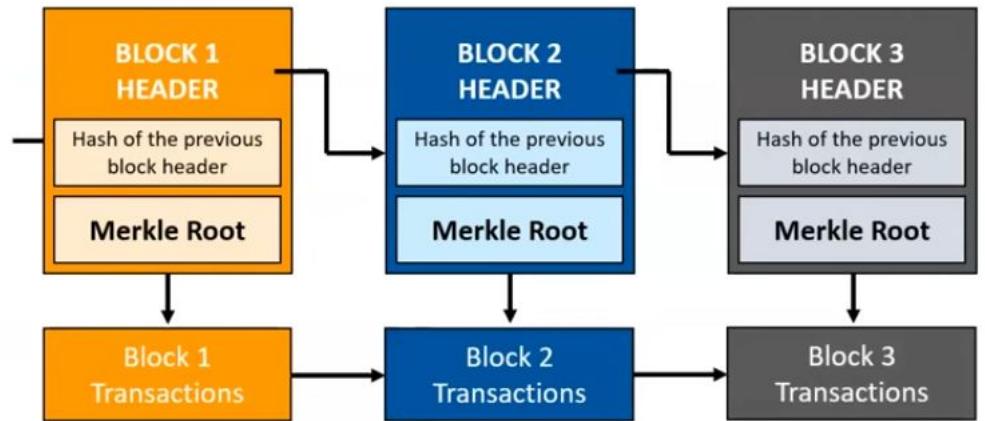

To confirm that there were no modifications, a computer used for validation would need a lot of computing power to compare ledgers.

1. Anatomy of a Blockchain - Block (Merkle Tree)

Why is it essential for Blockchain ?

Merkle Trees hash records in accounting, thereby separating the proof of data. Proving that given information across the network is all that is required for a transaction to be valid.

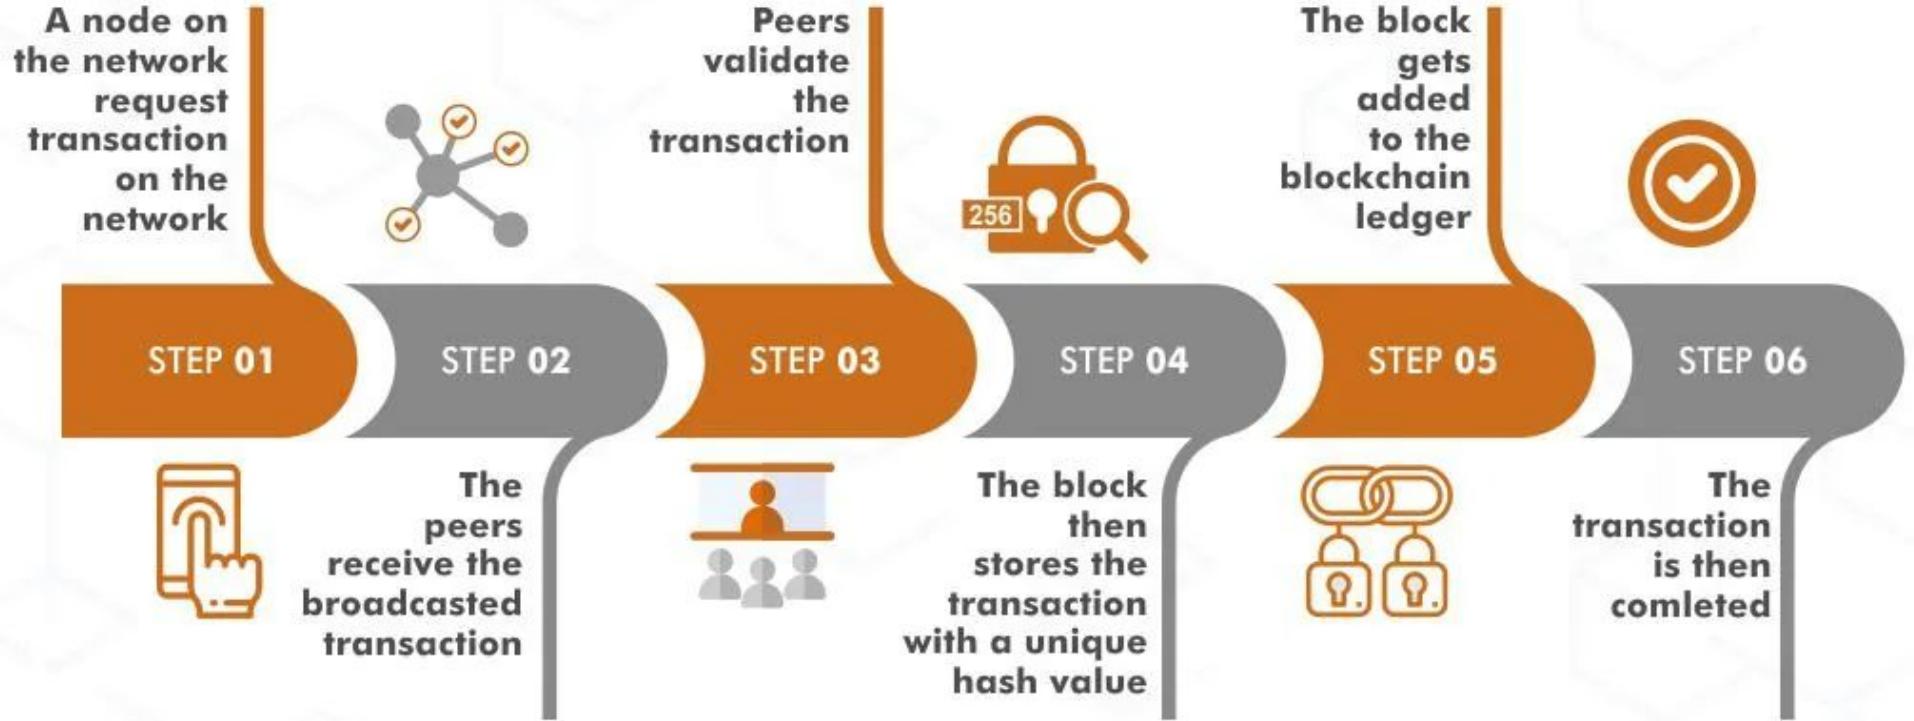

Merkle Tree breaking the data into tiny parts of information

1. Anatomy of a Blockchain - Transactions

- A transaction is a **transfer of value on the blockchain**.
- A transaction is **when one person gives a designated amount of cryptocurrency they own to another person**.
- To perform transactions on the blockchain, you need a crypto wallet.
- **Each wallet is protected by a special cryptographic method** that uses a **unique pair of distinct but connected keys: a private and a public key**.
 - A **public key / blockchain address**, is a **series of letters and numbers** that a user must share in order to receive funds.
 - **Private key** must be **kept secret**, much like your bank card pin number, as it **authorizes the spending of any funds received by the associated public key**.
- **With their wallet, a user** (whoever has the private key) **can authorize or sign transactions** and thereby transfer value to a new owner.
- The transaction is then broadcast to the network to be included in the blockchain.

1. Anatomy of a Blockchain - Transactions

Transactions in Blockchain - Life Cycle

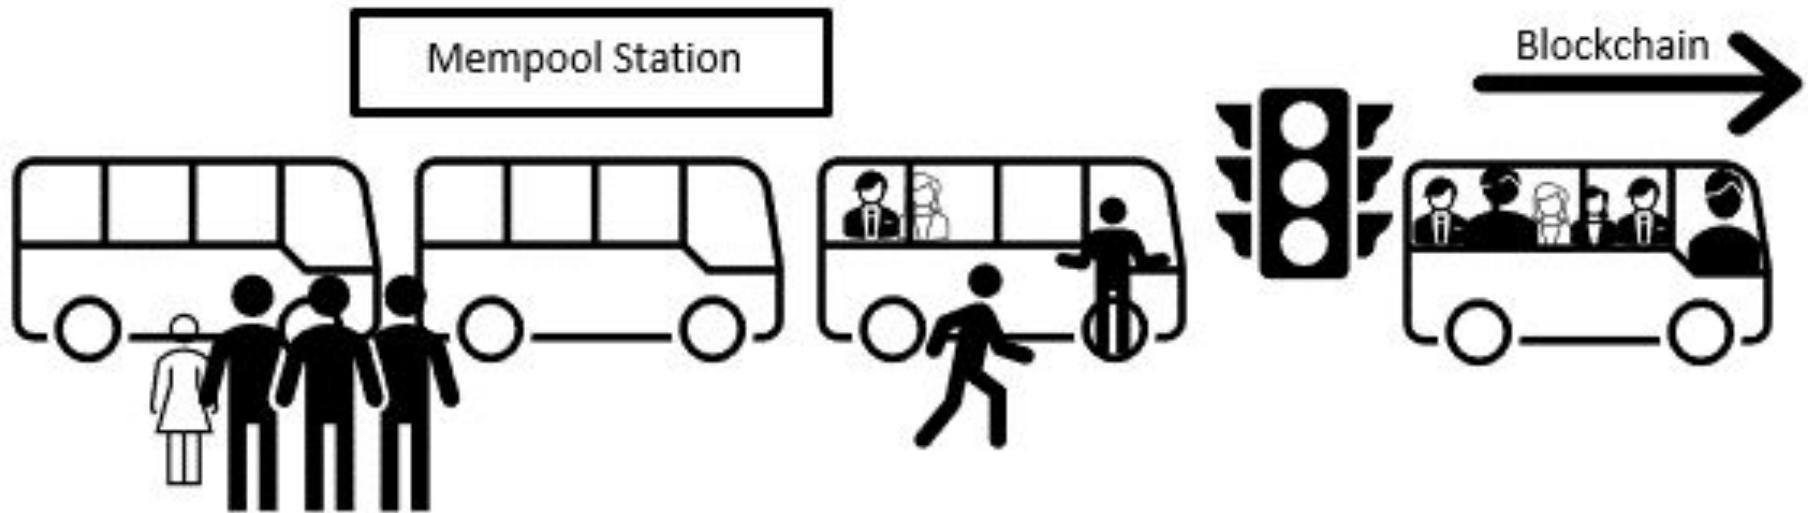

1. Anatomy of a Blockchain - Transactions

Transactions in Blockchain - Life Cycle

1. Someone requests a transaction. The transaction could involve cryptocurrency, contracts, records, or other information.
2. **Transaction is broadcast to all P2P** participation computers in the specific blockchain network. These are called **Nodes**. All transactions are published to the **Mempool** or memory pool, where they are considered 'pending'. **Gas fees** are paid by users as part of the transaction to compensate for the computing energy required to process and validate transactions on the blockchain.
3. **Miners** verify the transaction. Every computer in the network checks the transaction against some validation rules that are set by the creators of the specific blockchain network.
4. **Validated transactions** are stored into a block and are sealed with a lock referred to as the **Hash**.
5. **New block is added to the existing Blockchain**. This block becomes part of the blockchain when other computers in the network validate if the lock on the block is correct.
6. The transaction is complete. Now the transaction is part of the blockchain and cannot be altered in any way.

1. Anatomy of a Blockchain - Transactions

Transactions in Blockchain - The Bus Station Analogy

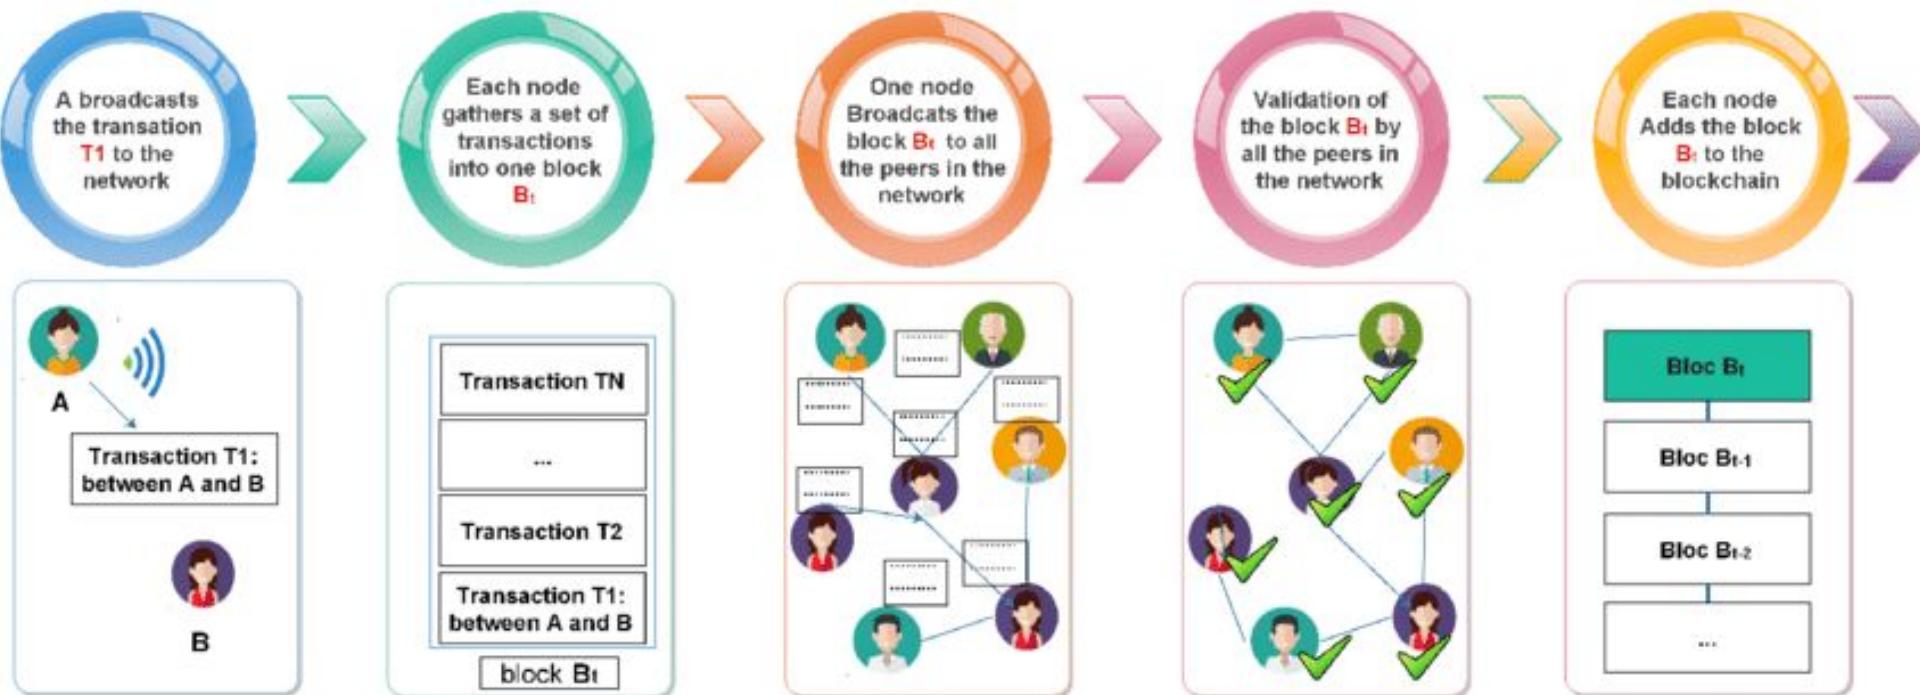

1. Anatomy of a Blockchain - Transactions

Transactions in Blockchain - Live Demo

1. Anatomy of a Blockchain - Transactions

Transactions in Blockchain - Example

1. Anatomy of a Blockchain - Transactions

Transactions in Blockchain - Example contd...

- Alice wants to send two coins to Bob.
 - Each transaction has **three main parts**:
 - **The input**: Alice's private coin address, she wants to spend.
 - **The output**: Bob's public key or coin address.
 - **Amounts**: the amount of coins Alice wants to spend.
1. **Alice signs a message with the transaction details using her private key.** The message contains the input, output, and amount to be sent.
 2. **The transaction is then broadcast to the network** saying the amount of coins in her account should go down by two. The amount in Bob's account should increase by two.
 3. **Each computer in the network will receive the message** and apply the requested transaction to its copy of the ledger, updating the account balances.
 4. **Add the transactions into the MemPool.**
 5. **Miner** select few transactions from MemPool and tries to **solve Cryptographic Puzzle**.
 6. On solving the Puzzle, the **Block is broadcasted to the network for validation**.
 7. After adding Block into the Blockchain, **Transactions added in the Block are later removed from MemPool**

I want to Buy a 2nd bicycle for 1.1 BTC

TRANSACTION:

Input:
 0.3 BTC from Hadelin,
 0.7 BTC from Susan,
 0.1 BTC from Me

Output:
 1.1 BTC to the bike shop.

Blockchain A-Z

1. Anatomy of a Blockchain - Transactions

UTXO - Unspent transaction output

- The fundamental building block of a bitcoin transaction
- Transaction outputs are **indivisible chunks of bitcoin currency**, recorded on the blockchain, and recognized as valid by the entire network.
- Bitcoin full nodes track all available and spendable outputs
- **UTXO set** - The collection of all UTXO
 - set grows as new UTXO is created
 - shrinks when UTXO is consumed.
- Every transaction represents a change (state transition) in the UTXO set.
- Eg:User receiving 1 BTC → wallet detected a UTXO that can be spent by any key in the wallet
- **Users Bitcoin balance = Sum of all UTXO** in the users wallet can detect in the network.
 1. scanning the Blockchain
 2. aggregating the **value of UTXO** that wallet can spent using the keys it stores.

1. Anatomy of a Blockchain - Transactions

UTXO - Unspent transaction output

- Have an arbitrary value denominated as a multiple of satoshis
- 1 BTC can be divided into 8 decimal places of satoshi.
- Can only be consumed in its entirety by a transaction.

Wallet Strategies to satisfy a purchase amount (done by the user wallet automatically)

- Combine several smaller units
- Finding exact change
- Using a single UTXO larger than the transaction value.

Coinbase

- Special type of transaction appears as the 1st transaction in each block.
- Placed / created by the miner as a reward for mining (**Bitcoin Money Supply is created**)
- Does not consume UTXO

1. Anatomy of a Blockchain - Transactions

UTXO - Unspent transaction output

- Every bitcoin transaction creates outputs, which are recorded on the bitcoin ledger.
- **Transaction outputs consist of two parts:**
 1. An amount of bitcoin, denominated in satoshis, the smallest bitcoin unit
 2. A cryptographic puzzle that determines the conditions required to spend the output
 - **locking script / witness script / scriptPubKey / P2PKH (Pay to Public Key Hash)**

Transaction Serialization

- Process of converting the internal representation of a data structure such that it can be transmitted one byte at a time

Transaction Deserialization / Parsing

- Process of converting byte stream representation of a transaction to internal representation of a data structure

1. Anatomy of a Blockchain - Transactions

Transaction inputs

- identify (by reference) which UTXO will be consumed
- provide proof of ownership through an [unlocking script / Digital Signature](#)

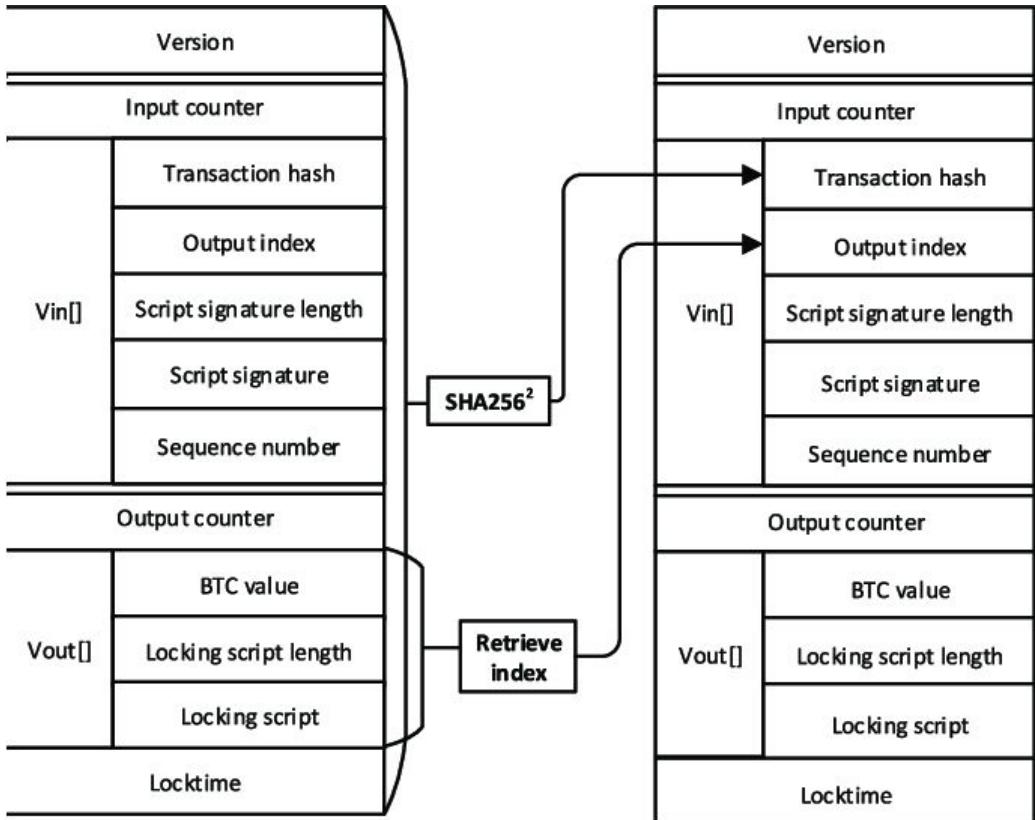

Transaction input contains four elements:

1. A transaction ID, referencing the transaction that contains the UTXO being spent
2. An output index (vout), identifying which UTXO from that transaction is referenced (first one is zero)
3. A scriptSig. which satisfies the conditions placed on the UTXO, unlocking it for spending
4. A sequence number

Note : Once a transaction is broadcasted, every validating node needs to retrieve the UTXO reference in the transaction inputs in order to validate the transaction.

1. Anatomy of a Blockchain - Transactions Structure

Courtesy : [Research Gate](#)
[Oreilly](#)

1. Anatomy of a Blockchain - Transactions

Transaction Fees

- Incentives given to the miner for mining blocks
- Disincentive against abuse of the system by imposing a small cost on every transaction
- Encourages processing priority
- Calculated :
 - Initially, based on the size of the transaction in KB (not on the value of the transaction)
 - Now, based on network capacity & transaction volume.
- MinRelayTxFee (Bitcoin) : Default : 0.00001 BTC
- If TxFee < MinRelayFee
 - ⇒ Transaction is free
 - ⇒ Relayed only if there is space in mempool / Dropped
- Transaction can have different levels of Priority based on TxFees
 - High ⇒ user pays high TxFees
 - Medium or Low ⇒ user pays low TxFees

1. Anatomy of a Blockchain - Transactions

Adding Transaction Fees to Transactions

- No field in Fees in the Transaction Structure
- TxFees = Excess amount that remains after all outputs have been deducted from all inputs
 - **TxFees = Sum(Inputs) - Sum(Outputs)**
- Ideal TxFees to ensure that transactions get confirmed and verified
 - **TxFees = size of Transaction * per KB fees**

Scenario - 1 : Alice has 0.2 BTC

- 0.015 BTC \Rightarrow UTXO to Bob
- 0.001 BTC \Rightarrow UTXO to Miner (as TxFees)
- 0.184 BTC \Rightarrow UTXO back to Alice

Scenario - 2 : Eugenia raising funds for Children's Charity (purpose purchase school books)

- collected 50 BTC as thousands of UTXO as TxInputs
- Pay the purchaser as one UTXO
- Pay higher TxFees as there are many small TxInputs so that transaction is processed promptly

1. Anatomy of a Blockchain - Transactions Live Bitcoin Block

Bitcoin Block 800,041

Mined on July 24, 2023 03:17:23 • All Blocks

Unknown

Coinbase Message • H>d/Foundry USA Pool #dropgold/lRq

A total of 234.86 BTC (\$6,978,185) were sent in the block with the average transaction being 0.0394 BTC (\$1,170.67). Unknown earned a total reward of 6.25 BTC \$185,703. The reward consisted of a base reward of 6.25 BTC \$185,703 with an additional 0.0696 BTC (\$2,067.99) reward paid as fees of the 5,967 transactions which were included in the block.

1. Anatomy of a Blockchain - Transactions

What is Segregated Witness ? (SegWit)

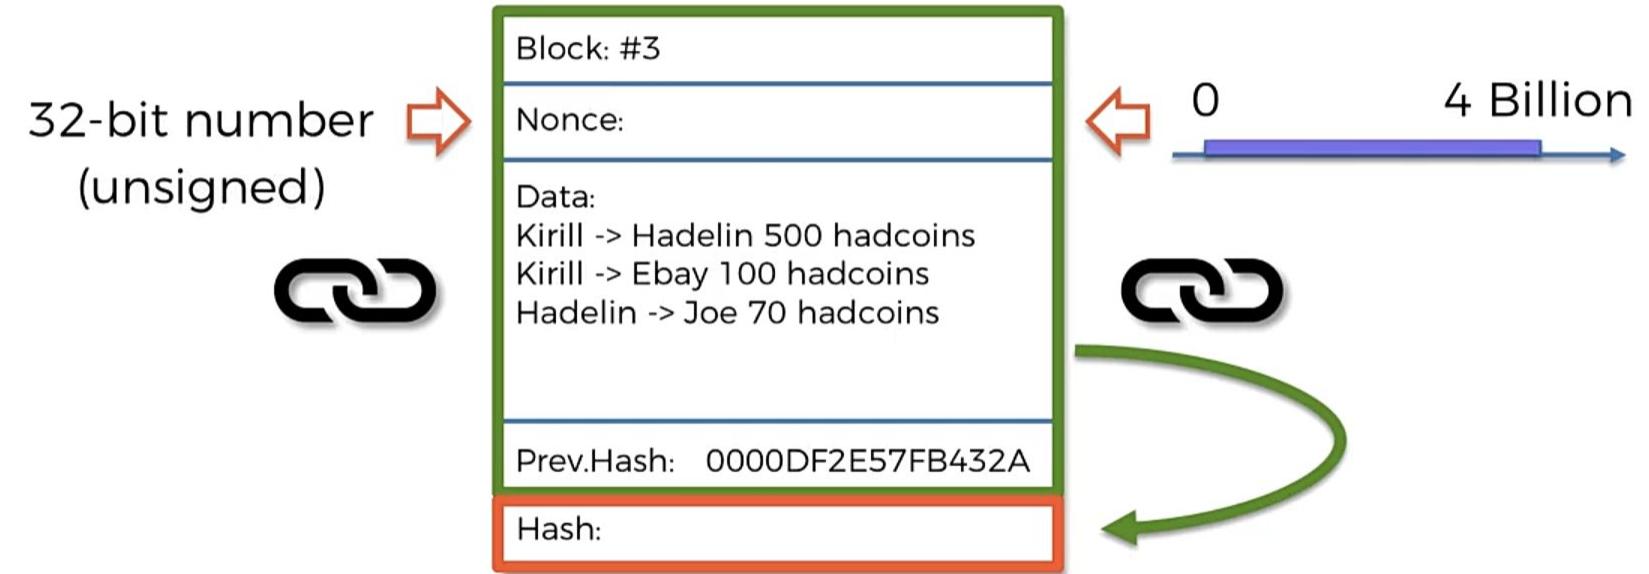

1. Anatomy of a Blockchain - Transactions

What is Segregated Witness ? (SegWit)

1. Anatomy of a Blockchain - Transactions

Nonce Range

1. Anatomy of a Blockchain - Transactions

Nonce Range

Let's do some estimations:

Difficulty:

Total possible 64-digit hexadecimal numbers: $16 \times 16 \times \dots \times 16 = 16^{64} \approx 10^{77}$

Total valid hashes (with 18 leading zeros): $16 \times 16 \times \dots \times 16 = 16^{64-18} \approx 2 \times 10^{55}$

Probability that a Randomly picked hash is valid: $2 \times 10^{55} / 10^{77} = 2 \times 10^{-22} = 0.0000000000000000000002\%$

Nonce:

The Nonce is a 32-bit number, the Max Nonce = $2^{32} = 4,294,967,296 = 4 \times 10^9$

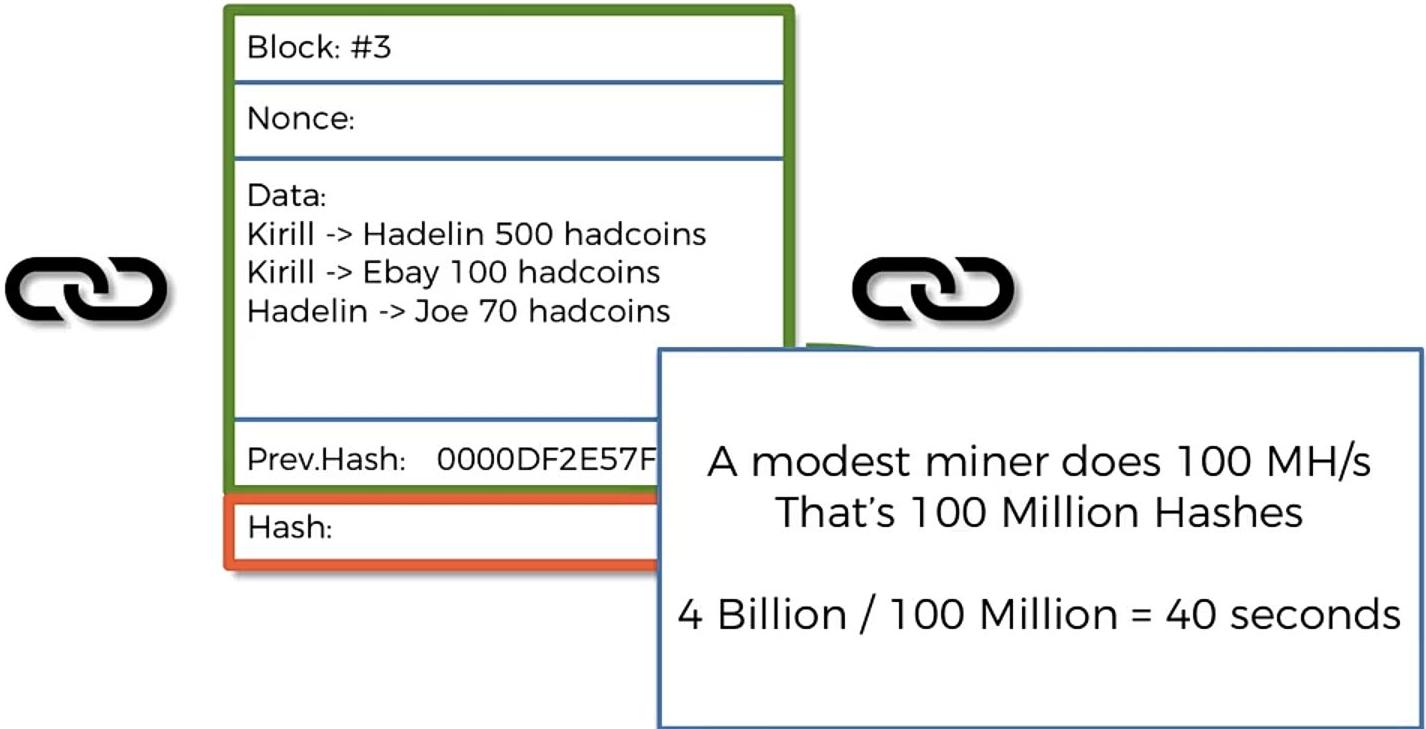

Assuming no collisions, this means 4×10^9 different hashes

Probability that ONE of them will be valid: $4 \times 10^9 \times 2 \times 10^{-22} = 8 \times 10^{-13} \approx 10^{-12} = 0.0000000001\%$

Conclusion: One Nonce Range is not enough

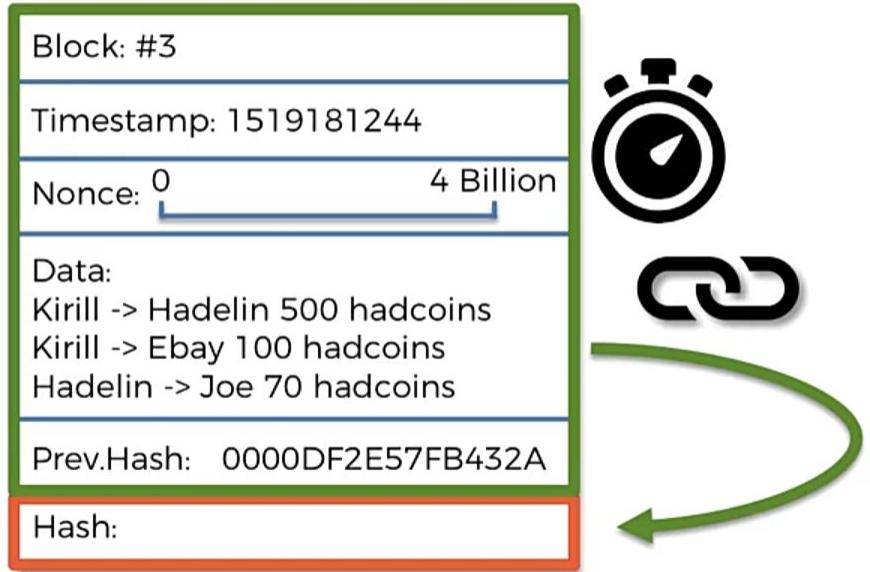

1. Anatomy of a Blockchain - Transactions

How does Miner Picks transactions?

(Mining in Process)

1. Anatomy of a Blockchain - Mining Machines

CPU, GPUs and ASIC

CPU = Central Processing Unit

General

< 10 MH/s

GPU = Graphics Processing Unit

Specialized

< 1 GH/s

ASIC = Application-Specific Integrated Circuit

Totally Specialized

> 1,000 GH/s

Cloud Mining

1. Anatomy of a Blockchain - Life of Miners

ASIC (Application-specific integrated circuits) Miners

- most effective and powerful mining hardware
- Manufacturers build these machines with the sole purpose of mining a specific crypto algorithm
- As mining is an intensive and competitive process, it pushes these machines to their **maximum capabilities**.
- The average lifespan of a well-maintained machine : **3 to 5 years**.
- If kept in harsh or poor conditions, they can deteriorate in **a few months**.

1. Anatomy of a Blockchain - Life of Miners

Common causes for ASIC damage and deterioration are:

1. Little or no airflow:

- ASIC miners release a considerable amount of heat,
- crucial to keep and run them in a well-ventilated location that keeps air moving and refreshing to avoid overheating.

2. Humid, damp, or moist environments:

- internal components are damaged by humidity, which can cause rust and corrosion.

3. Extreme temperatures:

- can shorten your hardware's lifespan by chipping away its internal components.
- Cold tends to be less critical, as ASICs release heat that can counter-balance it.
- Quick swings from below-zero to warm temperatures can cause condensation, provoking irreversible damage.

1. Anatomy of a Blockchain - Life of Miners

Best practices for preserving ASIC miners

1. Choosing a suitable location

- it must be a **dry** room with good, constant **airflow**, so **wide and open spaces** should be the first choice.
- consider **installing additional fans** to keep the air moving, maintain the room dry, and avoid condensation.

2. Mitigating the heat

- specialized and advanced cooling systems that reduce temperature,
- innovative ways to **repurpose the heat produced by ASIC machines**, like heating pools or hot tubs, dehydrating fruit, or redirecting it to greenhouses for growing crops.
 - reduce or even eliminate the damage high temperatures have on miners,
 - enable **increased profitability** either by **reducing costs or adding another source of income**.
 - primary priority is **treating the excess heat** to preserve your miners.

3. Regular maintenance and cleaning

- It is essential to **perform regular maintenance and clean the mining hardware**.
- Removing accumulated dust not only prolongs lifespan, but also keeps performance high.

1. Anatomy of a Blockchain - Nodes

WHAT ARE NODES?

Nodes are the electronic devices connected to the network and possessing an IP address. Generally, nodes are the communication endpoints which means that any user or application that wants to interact with the blockchain does so through nodes.

WHAT DOES A BLOCKCHAIN NODE DO?

Processing A Transaction

Managing the transactions
and their validity

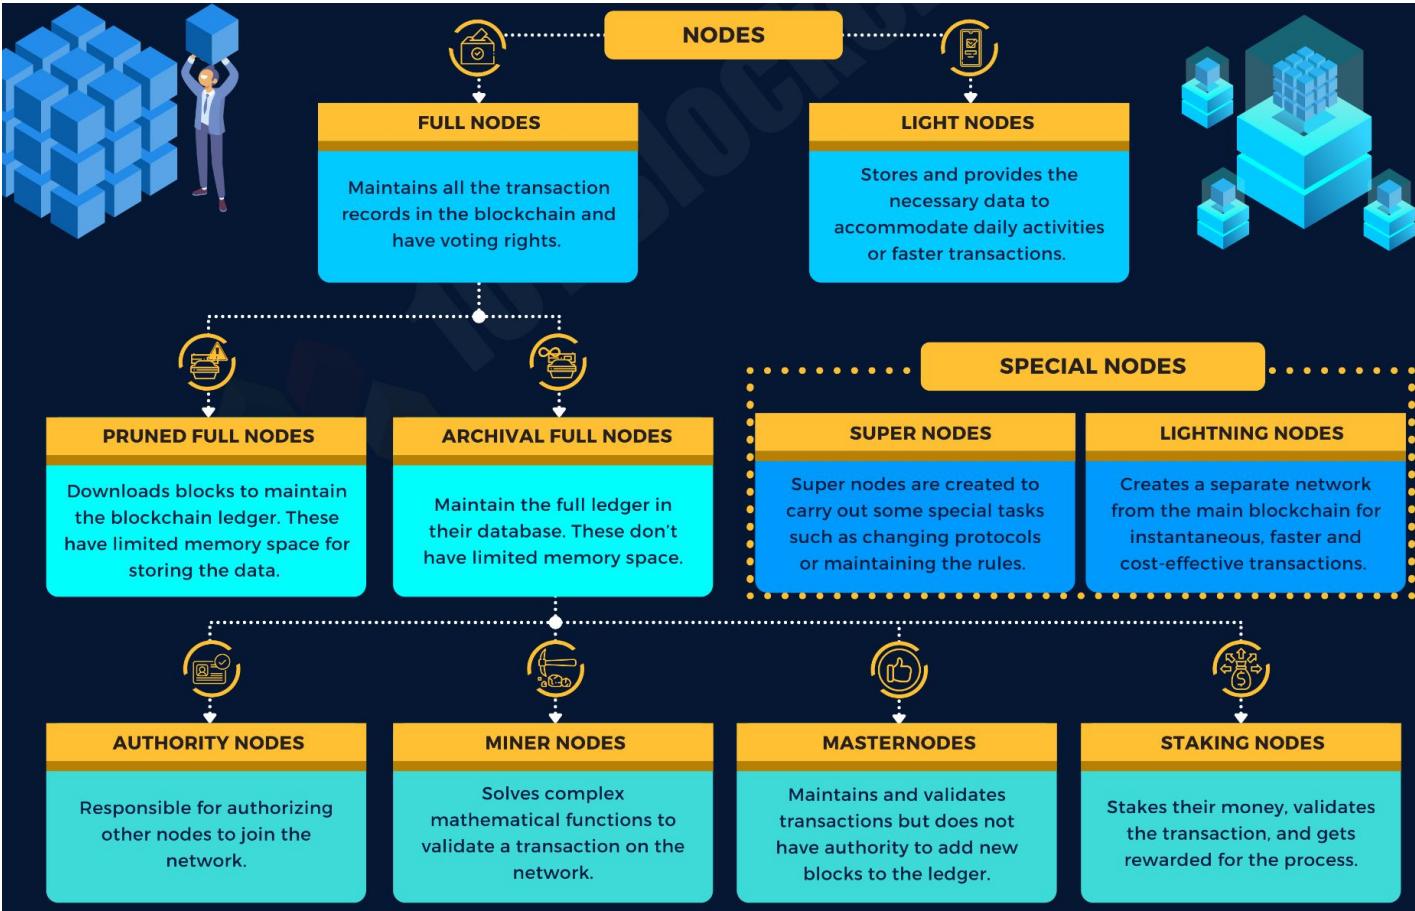

Storing the cryptographically
linked blocks

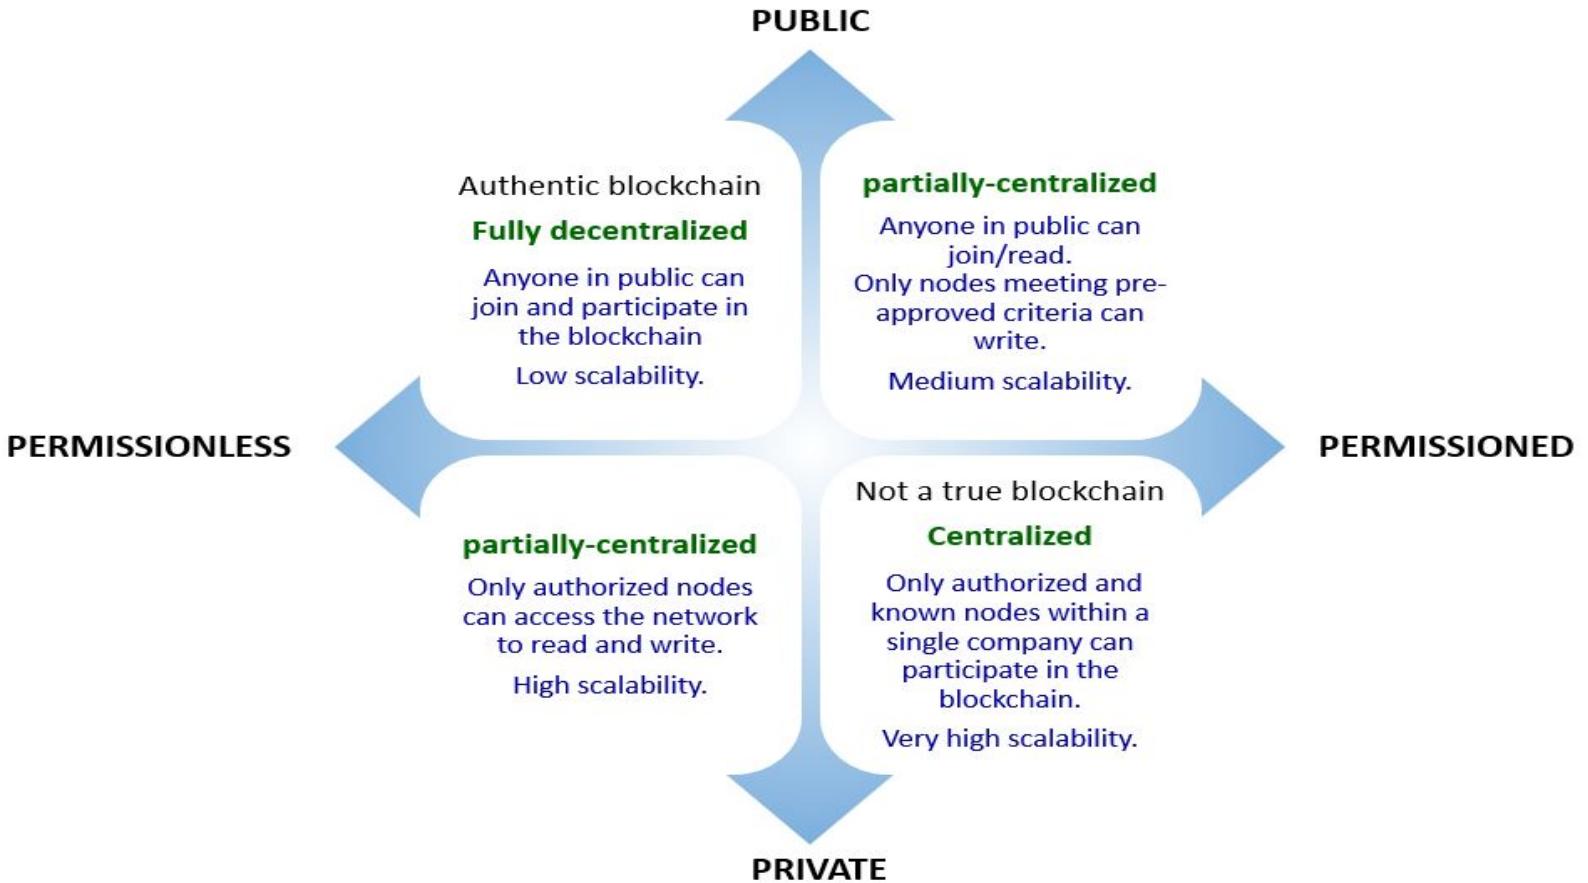

Acting as a point of
communication

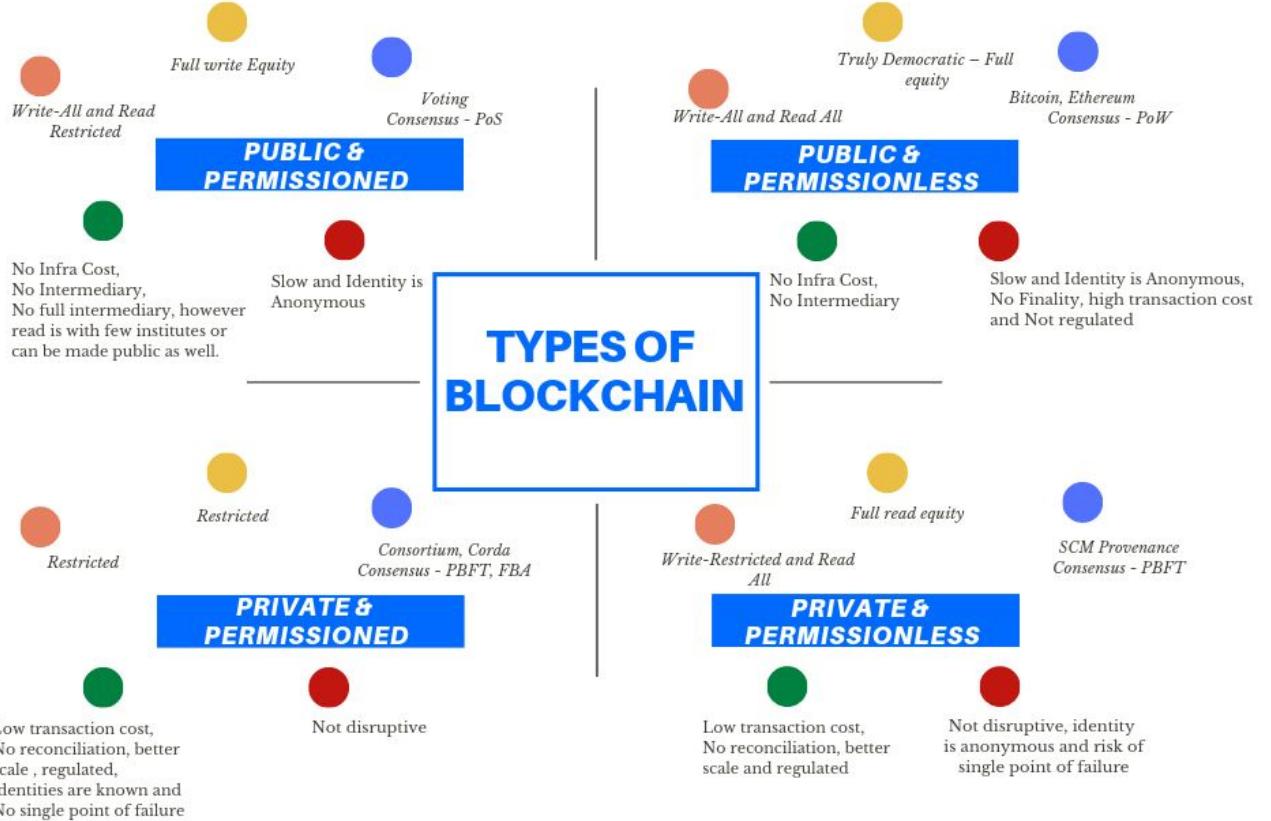

1. Anatomy of a Blockchain - Nodes

2. Types of Blockchains

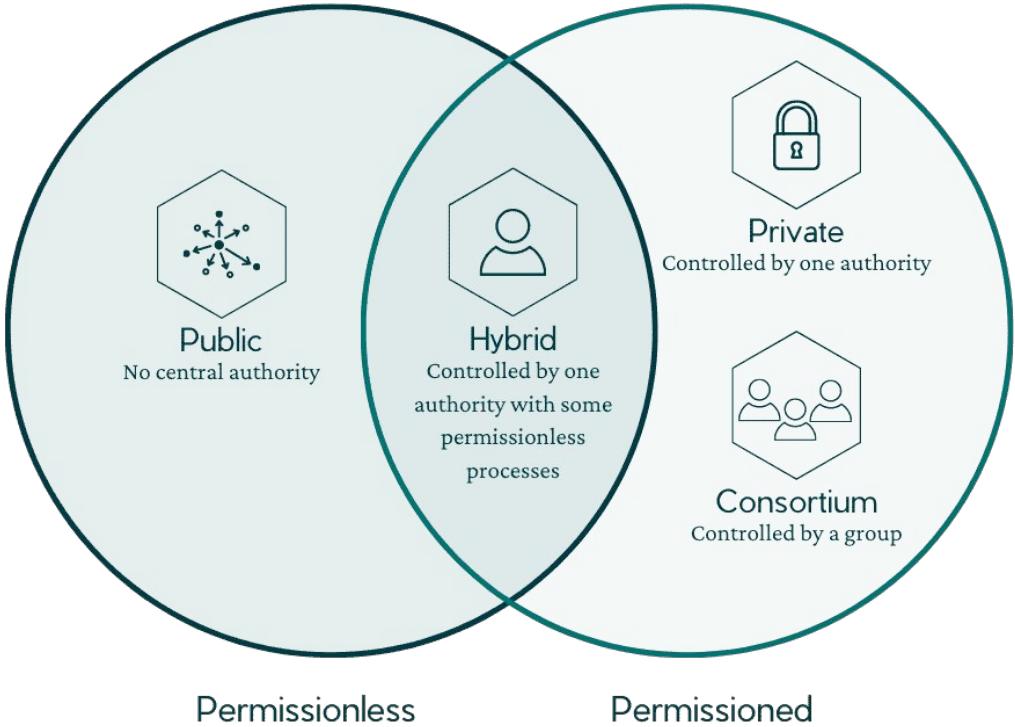

2. Types of Blockchains

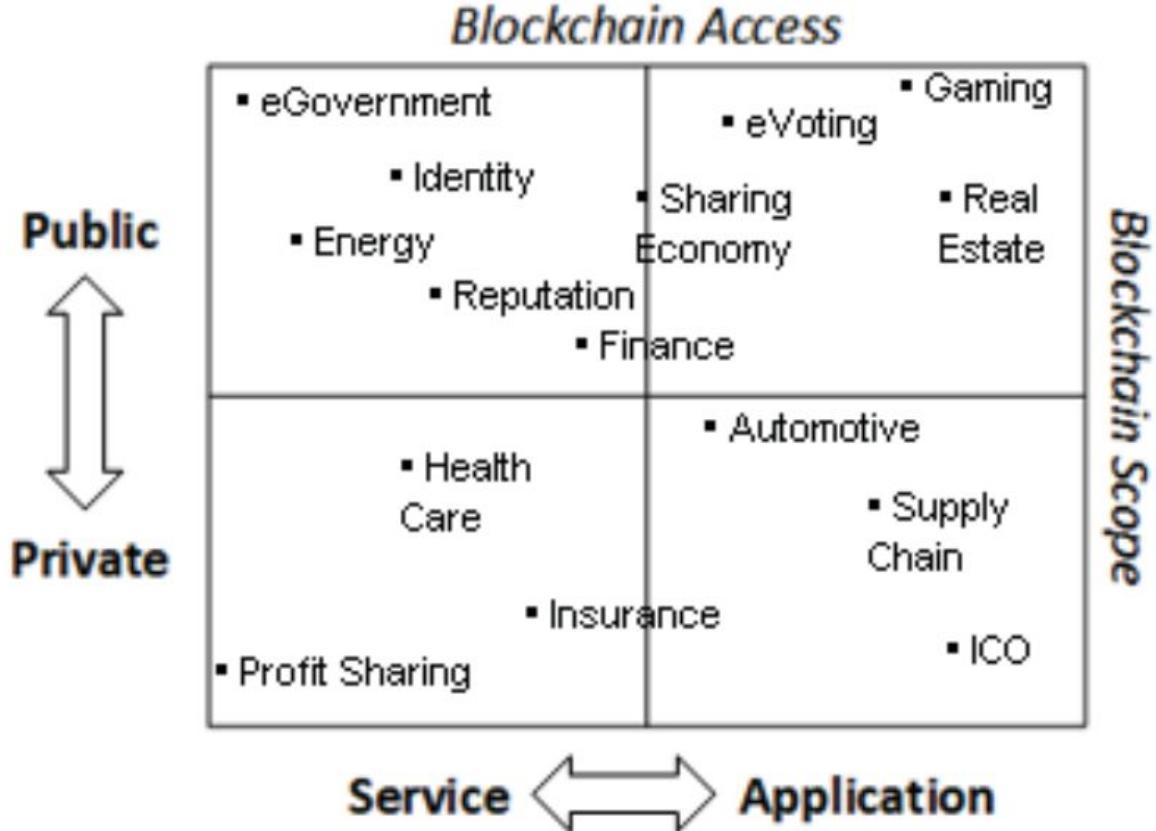

2. Types of Blockchains

ELEVATE X

2. Types of Blockchains

2. Types of Blockchains

| | Public (permissionless) | Private (permissioned) | Hybrid | Consortium |
|---------------|--|-------------------------------------|--|---|
| ADVANTAGES | + Independence + Transparency + Trust | + Access control + Performance | + Access control + Performance + Scalability | + Access control + Scalability + Security |
| DISADVANTAGES | - Performance - Scalability - Security | - Trust - Auditability | - Transparency - Upgrading | - Transparency |
| USE CASES | ■ Cryptocurrency ■ Document validation | ■ Supply chain ■ Asset ownership | ■ Medical records ■ Real estate | ■ Banking ■ Research ■ Supply chain |

3. Exploring Key Blockchain Platforms - Need

Key aspects that make blockchain platforms appealing:

1. Decentralization:

- Traditional systems often rely on a central authority, like a bank or government, to validate and record transactions.
- In a blockchain, the ledger is distributed across a network of nodes, eliminating the need for a central authority.

2. Security:

- Blockchain uses cryptographic techniques to secure transactions and control the creation of new units.
- The decentralized and consensus-based nature of blockchain makes it resistant to tampering and fraud.
- Once a block is added to the chain, it is extremely difficult to alter previous blocks, enhancing the overall security of the system.

3. Transparency:

- All participants in a blockchain network have access to the same information.
- This transparency helps build trust among users, as they can independently verify the transactions and data stored on the blockchain.

3. Exploring Key Blockchain Platforms - Need

4. Immutability:

- Once a block is added to the blockchain, it becomes very difficult to change.
- This immutability ensures that historical transactions are preserved and cannot be altered, providing a reliable and auditable record of events.

5. Smart Contracts:

- Smart contracts are self-executing contracts with the terms of the agreement directly written into code.
- They automatically execute and enforce the terms when predefined conditions are met, eliminating the need for intermediaries.

6. Efficiency and Cost Reduction:

- Blockchain can streamline and automate processes, reducing the need for intermediaries and minimizing the associated costs.
- The decentralized nature of blockchain also eliminates the single point of failure found in centralized systems, improving overall system reliability.

7. Global Accessibility:

- Blockchain operates on a global network, allowing participants from different parts of the world to engage in transactions without the need for intermediaries or traditional banking systems.
- This can be particularly beneficial for cross-border transactions.

3. Exploring Key Blockchain Platforms - Need

8. Tokenization:

- Blockchain enables the creation of digital tokens, representing various assets such as real estate, art, or even shares in a company.
- This facilitates new forms of ownership, investment, and crowdfunding.

9. Data Integrity:

- Blockchain ensures data integrity by design.
- Each block contains a unique identifier (hash) and references the previous block's hash.
- This interconnection makes it extremely difficult for malicious actors to alter data without detection.

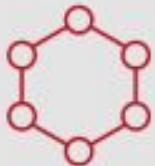

10. Use Cases:

- Blockchain has found applications in various industries, including finance (cryptocurrencies like Bitcoin and decentralized finance platforms), supply chain management, healthcare (patient data management), voting systems, and more

Blockchain Platform Types

Permissionless

Public

No central authority

Hybrid

Controlled by one authority with some permissionless process

Permissioned

Private

Controlled by one authority

Consortium

Controlled by a group

Blockchain Platform Types

| | Permissioned | Permissionless |
|-------------------|--|----------------------------|
| Preferred Purpose | Popular among industry-level firms and enterprises | Popular for public use |
| Decentralization | Limited decentralization | Broad decentralization |
| Development | Generally proprietary | Generally open source |
| Transparency | Less transparent | More transparent |
| Use cases | Manage supply chains Create contracts Verify payment between parties | Cryptocurrency blockchains |

Blockchain Platform Types (3 / 11)

- Categorized into several types based on their design, consensus mechanisms, and use cases.
- Common types of blockchain platforms:

1. Public Blockchains:

- Open to anyone.
- Decentralized and distributed ledger.
- Examples: Bitcoin, Ethereum.

2. Private Blockchains:

- Restricted access to a specific group or organization.
- Often used for internal purposes or within a consortium.
- Offers more control over the network.
- Examples: Hyperledger Fabric, Corda.

3. Consortium Blockchains:

- Semi-decentralized, involving a group of organizations.
- Shared control among multiple entities.
- Enhances efficiency through collaboration.
- Examples: R3 Corda (which can be used both as private and consortium).

4. Permissionless Blockchains:

- Anyone can join and participate.
- Typically associated with public blockchains.
- Examples: Bitcoin, Ethereum.

5. Permissioned Blockchains:

- Participants are known and must have permission to join.
- Offers more privacy and control.
- Common in private and consortium blockchains.
- Examples: Hyperledger Fabric, Quorum.

6. Smart Contract Platforms:

- Allows the execution of smart contracts.
- Automated, self-executing contracts with the terms written into code.
- Examples: Ethereum, Binance Smart Chain.

7. Cryptocurrency Platforms:

- Focused on the creation and management of digital currencies.
- Often includes a native cryptocurrency.
- Examples: Bitcoin, Litecoin.

8. Supply Chain Blockchain:

- Designed for tracking and managing supply chain activities.
- Improves transparency and traceability.
- Examples: IBM Food Trust, VeChain.

9. Identity Management Blockchains:

- Focuses on secure and decentralized identity verification.
- Helps prevent identity theft and fraud.
- Examples: Sovrin, uPort.

10. Cross-Chain Platforms:

- Allows interoperability between different blockchains.
- Enables the transfer of assets and data between blockchains.
- Examples: Polkadot, Cosmos.

11. Tokenization Platforms:

- Used for creating and managing digital tokens.
- Enables the representation of real-world assets on the blockchain.
- Examples: Ethereum (with ERC-20, ERC-721 standards), Binance Smart Chain.

Blockchain Platform Types - Public Blockchain

- completely permissionless.
- Blockchain networks are decentralised, meaning that no single organisation or individual lies at the center of it, controlling it and users can remain anonymous.
- With no permissions, anyone has the liberty to join and participate in the primary activities of a public blockchain.
- That's why public blockchains are known to be self-governed because users have complete freedom to read, write and audit activities on its network.
- **Main features of public blockchain:**
 - Permissionless
 - Largely decentralised
 - Self-governed
 - Maintains anonymity of users
- **Examples of public blockchain:**
 - [Bitcoin](#)
 - [Ethereum](#)
 - [Litecoin](#)

Blockchain Platform Types - Private Blockchain

- it requires users on its network to be verified.
- Users can only join such a network through invitation when their identity is authenticated.
- They are also given express permission on the level of access they have and the activities they can perform. This means that private blockchains have a single central authority or owner that controls granting access to it and also has the right to override, edit, or delete entries on the blockchain when it deems necessary.
- This results in the network being partially decentralized and smaller than public blockchains because of restricted access and central control.
- However, on the upside, this also means that the networks are fast, efficient and trusted.
- **Main features of private blockchain:**
 - Permissioned
 - Partially decentralised
 - Highly efficient
 - Trusted network
- **Example of private blockchain:**
 - Linux Foundation's [Hyperledger Fabric](#)

Blockchain Platform Types - Hybrid Blockchain

- Amalgamation of a private and public blockchain, combining the best of both networks into one.
- It has the capability of constructing a private, permissioned based system alongside a public, permissionless one.
- This creates a network that is not restricted by one blockchain's limitations
- Allows a single owner or central authority to control who has access to certain data and what is made public.
- **Main features of hybrid blockchain:**
 - Controlled by a central authority
 - A combination of permissioned and permissionless blockchain
 - Information can be accessed via smart contracts
- **Example of hybrid blockchain:**
 - XRP token

Blockchain Platform Types - Consortium Blockchain

- Known as **federated blockchain**,
- Another type of permissioned blockchain with its main point of differentiation being that it is a group of private blockchains owned by multiple individuals or entities.
- While each organisation manages their own blockchain in a consortium blockchain,
- it also allows data from several different sources to be integrated while ensuring a secure and efficient data flow.
- **Main features of consortium blockchain:**
 - Permissioned
 - Partially Decentralized
 - Controlled by a group of entities
 - Privacy and security of data is ensured
- **Examples of consortium blockchain:**
 - R3's [Corda](#)
 - ConsenSys' [Quorum](#)

Blockchain Platform Types : Comparison

| | Public | Private | Hybrid | Consortium |
|---------------------------------|---------------------------------------|-----------------------------------|-----------------------------------|--|
| Permissioned/ Permissionless | Permissionless | Permissioned | Permissioned & Permissionless | Permissioned |
| Control | No control by a central authority | Control by a central authority | Control by a central authority | Control by multiple central authorities |
| Main Advantages | ✓ Independence ✓ Transparency | ✓ Performance ✓ Scalability | ✓ Performance ✓ Low Cost | ✓ Performance ✓ Security |
| Main Disadvantages | ✗ Performance ✗ Scalability Issues | ✗ Security ✗ Trust | ✗ Transparency ✗ Upgrading | ✗ Transparency |
| Examples | Bitcoin Litecoin | Hyperledger Fabric | XRP token | Corda Quorum |

Checklist for Choosing a Blockchain Platform

Centralized vs Decentralized

Decentralization's strengths are redundancy, data integrity and trustless transactions, which centralized systems mostly sacrifice for better performance, price and ease of use.

Consensus mechanism

The algorithms used to verify blocks in a chain have a big impact on performance, security and compatibility with other platforms.

Development tools

The depth and breadth of support for developers often determines a platform's practicality for building enterprise applications.

Private vs. public

AKA permissioned vs. permissionless, it largely determines performance, privacy and security-and what they cost.

Performance

Decentralized platforms typically have much slower performance than centralized ones.

Cost

Products that are ostensibly free can cost more than commercial ones to deploy and use.

Maturity

Mature platforms typically have stronger interoperability, vendor support and developer communities.

Smart contracts

Much of a platform's value comes from the programmability and automation in its smart contract features.

Top 5 Blockchain Platforms for 2025

1. **Ethereum** : popular for decentralized applications (dApps) and smart contracts,
Layer 2 scaling solutions.
2. **Solana**: exceptional transaction speed and low fees
(best for DeFi, NFTs, and high-performance applications).
3. **Hyperledger Fabric** :
 - popular permissioned, modular blockchain platform
 - designed for enterprise-grade applications (privacy and security requirements)
4. **Polkadot** : focus on **interoperability** between blockchains.
Uses parachains connected to a central relay chain.
blockchains that can securely communicate with each other.
5. **Binance Smart Chain (BNB Chain)** :
 - EVM-compatible and optimized for **fast, low-cost transactions**.
 - Strong DeFi adoption and easy migration from Ethereum.
 - Widely used for DApps and token ecosystems

Comparison on the Top Blockchain Platforms

| Feature | Ethereum | Hyperledger Fabric | Solana | Polkadot | BNB Chain |
|-------------------|-----------------------------|-----------------------------|-------------------------------|---------------------------|---------------------------|
| Type | Public | Permissioned | Public | Public | Public |
| Primary Use | DeFi, NFTs, DAOs, DApps | Enterprise & Govt solutions | High-speed DeFi, NFTs, Gaming | Interoperable blockchains | Low-cost DeFi & DApps |
| Smart Contracts | Yes (Solidity, Vyper) | Yes (Chaincode) | Yes (Rust, C) | Yes (Substrate-based) | Yes (Solidity – EVM) |
| Consensus | Proof of Stake (PoS) | Raft / PBFT | PoH + PoS | Nominated PoS | Proof of Staked Authority |
| Permission Model | Permissionless | Permissioned | Permissionless | Permissionless | Permissionless |
| Transaction Speed | Moderate (Layer-2 improves) | High | Very High | High | High |

Comparison on the Top 5 Blockchain Platforms

| Feature | Ethereum | Hyperledger Fabric | Solana | Polkadot | BNB Chain |
|---------------------|------------------|-------------------------|----------------|---------------------|--------------------|
| Transaction Cost | High / Variable | Low | Very Low | Low | Very Low |
| Decentralization | High | Low–Medium | Medium | High | Medium |
| Scalability | Via Layer-2s | Native | Native | Parachains | Native |
| Token Needed | ETH | No native token | SOL | DOT | BNB |
| Enterprise Adoption | Medium | Very High | Low–Medium | Medium | Medium |
| Governance | Community driven | Organization controlled | Foundation-led | On-chain governance | Binance influenced |

Bitcoin : Introduction

- Bitcoin is one of the **famous cryptocurrencies**.
- Bitcoin was found by **Satoshi Nakamoto**.
- Bitcoin is a **Peer-to-Peer Electronic cash system (2008)**
- Bitcoin is **not something physical**
- It is **easy to transport anywhere with low cost**
- **No third party (intermediary)**

Bitcoin : Introduction

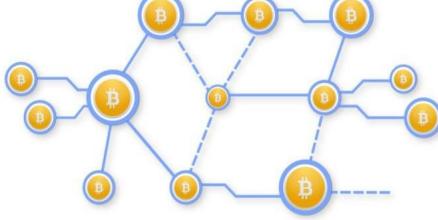

- It is a **decentralized digital currency without a central bank** that can be sent from user to user on the peer-to-peer bitcoin network without the need for intermediaries.
- Transactions are **verified by network nodes** through **cryptography** and recorded in a public distributed ledger called a **blockchain**.
- Launched in **2009**, Bitcoin is the **world's largest cryptocurrency** by market cap.

Why Bitcoin is Popular?

- It was the only cryptocurrency
- It is **decentralised currency** (Regulate by users, not any bank)
- It **allow user to do transaction anonymously**
- It is **tax free** (No matter how many bitcoins you have)
- **Transfer fund easily at very low cost**; Worldwide

Why Bitcoin is Popular?

www.newsbtc.com

- Bitcoin network is public - Source code is open source
- Owner uses **private key** to spend bitcoins
- **Public ledger:** All bitcoin exchanges are visible to everyone on the network
- Transfer/Spending of coins require very little fee
- Transactions are validated by miners who get rewarded

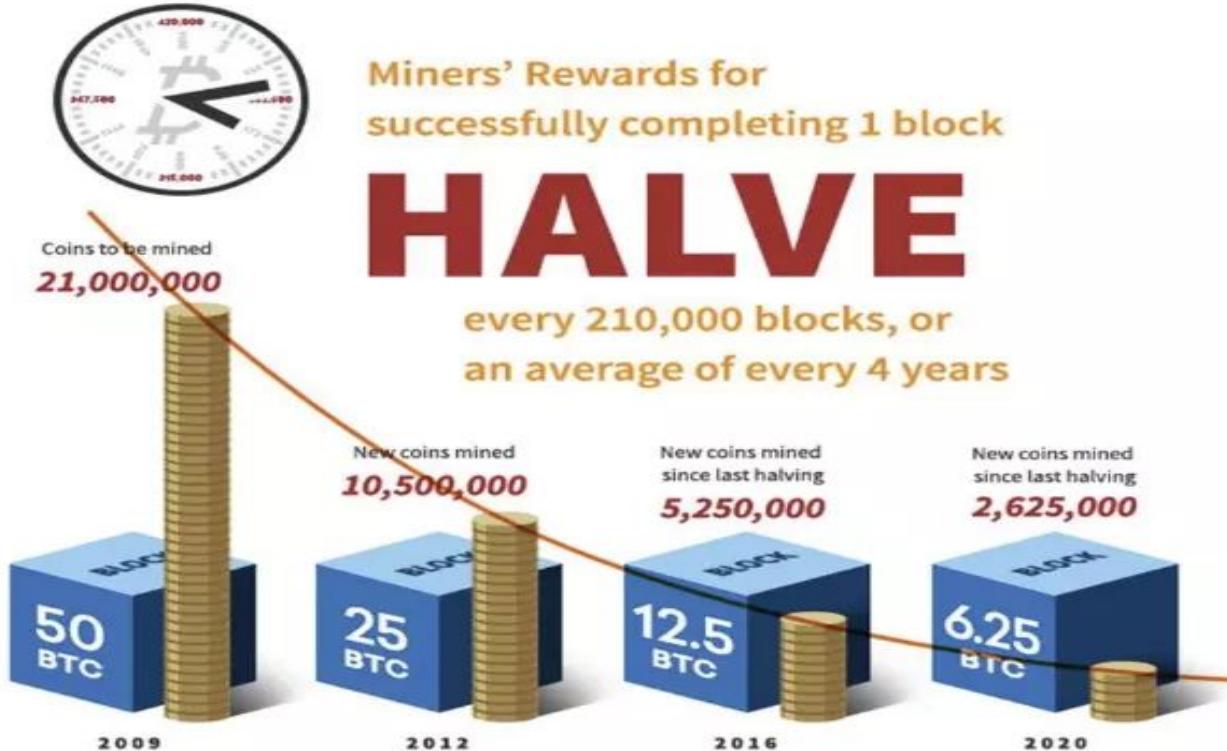

Bitcoin - denominations

| DENOMINATION | ABBREVIATION | FAMILIAR NAME | VALUE IN BTC |
|--------------|--------------|---------------------|----------------|
| Satoshi | SAT | Satoshi | 0.00000001 BTC |
| Microbit | µBTC (uBTC) | Microbitcoin or Bit | 0.000001 BTC |
| Millibit | mBTC | Millibitcoin | 0.001 BTC |
| Centibit | cBTC | Centibitcoin | 0.01 BTC |
| Decibit | dBTC | Decibitcoin | 0.1 BTC |
| Bitcoin | BTC | Bitcoin | 1 BTC |
| DecaBit | daBTC | Decabitcoin | 10 BTC |
| Hectobit | hBTC | Hectobitcoin | 100 BTC |
| Kilobit | kBTC | Kilobitcoin | 1000 BTC |
| Megabit | MBTC | Megabitcoin | 1000000 BTC |

Bitcoin - Monetary Policy

- Digital Currency Regulation
- Demand-supply
- The Halving every 4-year or after 2,10,000 blocks.
- The Block Frequency

Bitcoin - The Halving

What is Bitcoin?

- Bitcoin is a **completely decentralized, peer-to-peer, permissionless** cryptocurrency put forth in 2009
 - **Completely decentralized:** no central party for ordering or recording anything
 - **Peer-to-peer:** software that runs on machines of all stakeholders to form the system
 - **Permissionless:** no identity; no need to signup anywhere to use; no access control – anyone can participate in any role

* Nakamoto, Satoshi. "Bitcoin: A peer-to-peer electronic cash system." (2008)
<https://bitcoin.org/bitcoin.pdf>

The Permission-less Model

- Works in an **open environment** and over a large network of participants
- The users **do not need to know the identity of the peers**, and hence the users **do not need to reveal their identity** to others
- Good for **financial applications** like banking using cryptocurrency

Privacy - Security

- The system is tamper-proof – it is “**extremely hard**” to make a change in the blockchain
 - Tampering the system becomes harder as the chain grows
- For Bitcoin, the transactions are pseudo-anonymous
 - Transactions are sent to public key addresses,- cryptographically generated addresses, computed by the wallet applications

Peer Addresses

- “**Address**” in bitcoin is synonymous to an “**Account**” in a bank.
- The wallet listens for transactions addressed to an account,
 - Encrypts the transactions by the public key of the target address
 - Only the target node can decrypt the transaction and accept it
- However, the actual transaction amount is open to all for validation

What is Bitcoin?

The Bitcoin Ecosystem:

- Nodes

- Miners

- Large Mines

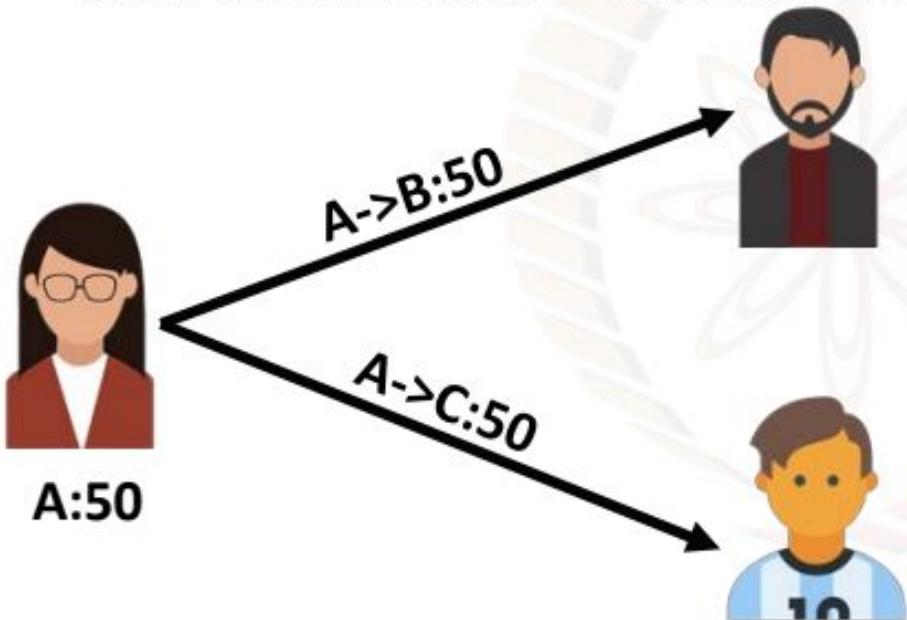

- Mining Pools

Bitcoin Basics - Double Spending

- Same bitcoin is used for more than one transactions

- In a centralized system, the bank prevents double spending
- How can we prevent double spending in a decentralized network?**

Bitcoin Basics - Handling Double Spending

- Details about the transaction are **sent and forwarded to all** or as many other computers as possible
- **Use Blockchain** – a constantly growing chain of blocks that contain a record of all transactions
- The blockchain is **maintained by all peers in the Bitcoin network** – everyone has a copy of the blockchain

Bitcoin Basics - Handling Double Spending

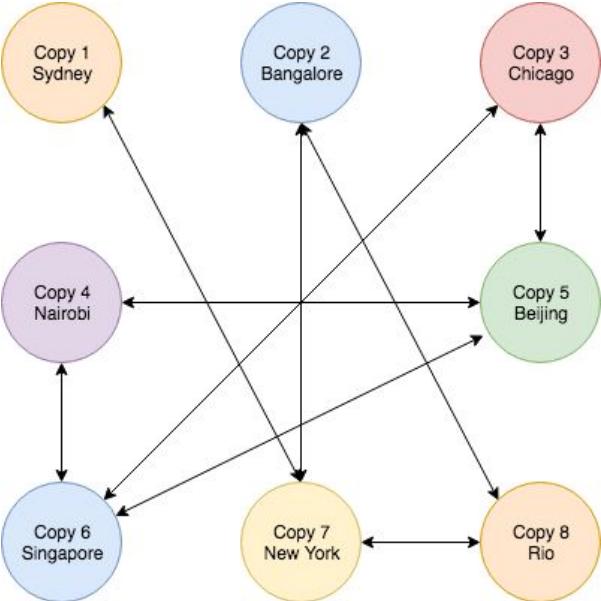

- To be accepted in the chain, transaction blocks must be valid and must include proof of work – a computationally difficult hash generated by the mining procedure
- Blockchain ensures that, if any of the block is modified, all following blocks will have to be recomputed

Bitcoin Basics - Handling Double Spending

- When multiple valid continuation to this chain appear, only the **longest such branch is accepted** and it is then extended further (longest chain)
- Once a **transaction is committed** in the blockchain, everyone in the network can validate all the transactions by using Alice's public address
- The **validation prevents double spending** in bitcoin

What is Ethereum?

- a public, blockchain based distributed computing platform.
- as one big computer made up of small computers around the world.
- Eg: One can write applications and run them on this global computer.
- The platform **guarantees that your application will always run without any downtime, censorship, fraud or third-party interference.**
- Ethereum blockchain can **also transfer money between 2 parties without a central authority**

What is Ethereum?

- A Blockchain network that introduced a built-in **Turing-complete programming language** that can be **used for creating** various decentralized applications(also called **Dapps**).
- Ethereum network is fueled by its own **cryptocurrency called ‘ether’**.
- Allow the implementation of **smart contracts**. Smart contracts can be thought of as ‘cryptographic bank lockers’ which contain certain values.
- These cryptographic lockers can only be unlocked when certain conditions are met.
- Ethereum is a network that can be applied to various other sectors.
- called **Blockchain 2.0** → it proved that blockchain can be used beyond the financial sector.
- The consensus mechanism used in Ethereum is **Proof of Stakes(PoS)**, which is **more energy efficient** than, **Proof of Work(PoW)**.
- PoS depends on the **amount of stake a node holds**.

History of Ethereum

2013:

- Ethereum was **first described** in Vitalik Buterin's white paper
- Goal of developing decentralized applications.

2014:

- **EVM was specified** in a paper by Gavin Wood, and the formal development of the software also began.

2015:

- Ethereum **created its genesis block** marking the official launch of the platform.

2018:

- Ethereum **took second place** in Bitcoin in terms of market capitalization.

2021:

- a major network upgrade named **London included Ethereum improvement proposal 1559**
- **introduced a mechanism** for reducing transaction fee volatility.

2022:

- Ethereum has **shifted from PoW(Proof-of-Work) to PoS(Proof-of-State)**
- Also known as **Ethereum Merge**.
- It has **reduced Ethereum's energy consumption** by ~ 99.95%.

Features of Ethereum

1. Smart contracts:
 - a. Ethereum allows the creation and deployment of smart contracts.
 - b. Smart contracts are created mainly using a programming language called **solidity**.
2. Ethereum Virtual Machine (EVM):
 - a. **a runtime environment for compiling and deploying Ethereum-based smart contracts**.
3. Ether:
 - a. **cryptocurrency of the Ethereum network**.
 - b. **only acceptable form of payment for transaction fees** on the Ethereum network.
4. Decentralized applications (Daaps):
 - a. **has its backend code running on a decentralized peer-to-peer network**.
 - b. Has a frontend and UI to make calls and query data from its backend.
 - c. They **operate on Ethereum** and **perform the same function irrespective of the environment** in which they get executed.
5. Decentralized autonomous organizations (DAOs):
 - a. **works in a democratic and decentralized fashion**.
 - b. **relies on smart contracts for decision-making** within the organization.

Real-World Applications of Ethereum

1.

Voting:

- a. Voting systems are **adopting Ethereum**.
- b. The **results of polls are available publicly, ensuring a transparent fair system thus eliminating voting malpractices**.

2.

Agreements:

- a. With Ethereum smart contracts, agreements and contracts **can be maintained and executed without any alteration**.
- b. Ethereum can be **used for creating smart contracts and for digitally recording transactions based on them**.

3.

Banking systems:

- a. Due to the **decentralized nature** of the Ethereum blockchain it becomes **challenging for hackers to gain unauthorized access to the network**.
- b. **Makes payments on the Ethereum network secure**

4.

Shipping:

- a. Ethereum provides a tracking framework that helps with the **tracking of cargo and prevents goods from being misplaced**.

5.

Crowdfunding:

- a. **helps to increase trust and information symmetry**.
- b. **It creates many possibilities for startups by raising funds to create their own digital cryptocurrency**.

Hyperledger

- An open-source collaborative effort aimed at advancing cross-industry blockchain technologies.
- Hosted by The Linux Foundation, Hyperledger brings together a diverse community of developers and organizations to collaborate on the development of modular frameworks and tools for enterprise-grade blockchain solutions.
- The project was launched in December 2015 and has since grown to include a variety of blockchain frameworks, libraries, and tools.
- **Key components and features of Hyperledger**

1. Collaborative Ecosystem:

- Hyperledger fosters a collaborative and vendor-neutral environment, bringing together contributors from various industries, including finance, healthcare, supply chain, and more. It encourages open participation and contributions from individuals and organizations.

Hyperledger

Distributed Ledgers

Java-based
Ethereum client

Permissionable smart
contract machine (EVM)

Enterprise-grade DLT
with privacy support

Mobile application focus

Permissioned & permissionless
support; EVM transaction family

Libraries

Tools

Domain-Specific

2. Modular Frameworks:

- Hyperledger provides a range of modular blockchain frameworks, each designed to meet specific enterprise use cases. Notable frameworks include:
 - Hyperledger Fabric: A permissioned blockchain framework with a modular architecture, supporting plug-and-play components for consensus algorithms, membership services, and more.
 - Hyperledger Sawtooth: A modular and scalable framework with a unique consensus algorithm called Proof of Elapsed Time (PoET).
 - Hyperledger Besu: An Ethereum-compatible client designed for enterprise use within the Hyperledger consortium.
 - Hyperledger Indy: Focused on decentralized identity, enabling the creation of self-sovereign identities.

3. Permissioned Blockchains:

- Hyperledger frameworks are generally designed for permissioned blockchains, where participants are known entities and have defined roles and permissions. This approach is well-suited for enterprise use cases, emphasizing privacy, scalability, and performance.

4. Smart Contracts and Chaincode:

- Hyperledger Fabric supports smart contracts, referred to as "chaincode," which are written in languages like Go, JavaScript, or Java. Chaincode allows the execution of business logic on the blockchain.

5. Consensus Mechanisms:

- Hyperledger frameworks offer flexibility in choosing consensus mechanisms. Hyperledger Fabric, for example, supports various consensus algorithms, including Practical Byzantine Fault Tolerance (PBFT), Raft, and others.

6. Interoperability and Standards:

- Hyperledger emphasizes interoperability and collaboration between different blockchain networks. It aims to establish common standards to facilitate seamless integration between various Hyperledger frameworks and other blockchain technologies.

7. Identity and Privacy:

- Hyperledger Indy focuses specifically on decentralized identity solutions, providing tools and libraries for creating and managing self-sovereign identities. Privacy and identity protection are critical considerations in Hyperledger projects.

8. Open Source and Apache 2.0 License:

- All Hyperledger projects are released under the open-source Apache 2.0 license, promoting transparency, accessibility, and collaboration within the community.

9. Enterprise Adoption:

- Hyperledger frameworks are designed with enterprise requirements in mind, such as scalability, performance, and compliance with regulatory standards. This focus has led to widespread adoption in industries seeking to leverage blockchain technology for various use cases.

10. Education and Community Support:

- Hyperledger offers educational resources, including documentation, tutorials, and training programs, to help developers and organizations understand and implement blockchain solutions using Hyperledger frameworks.

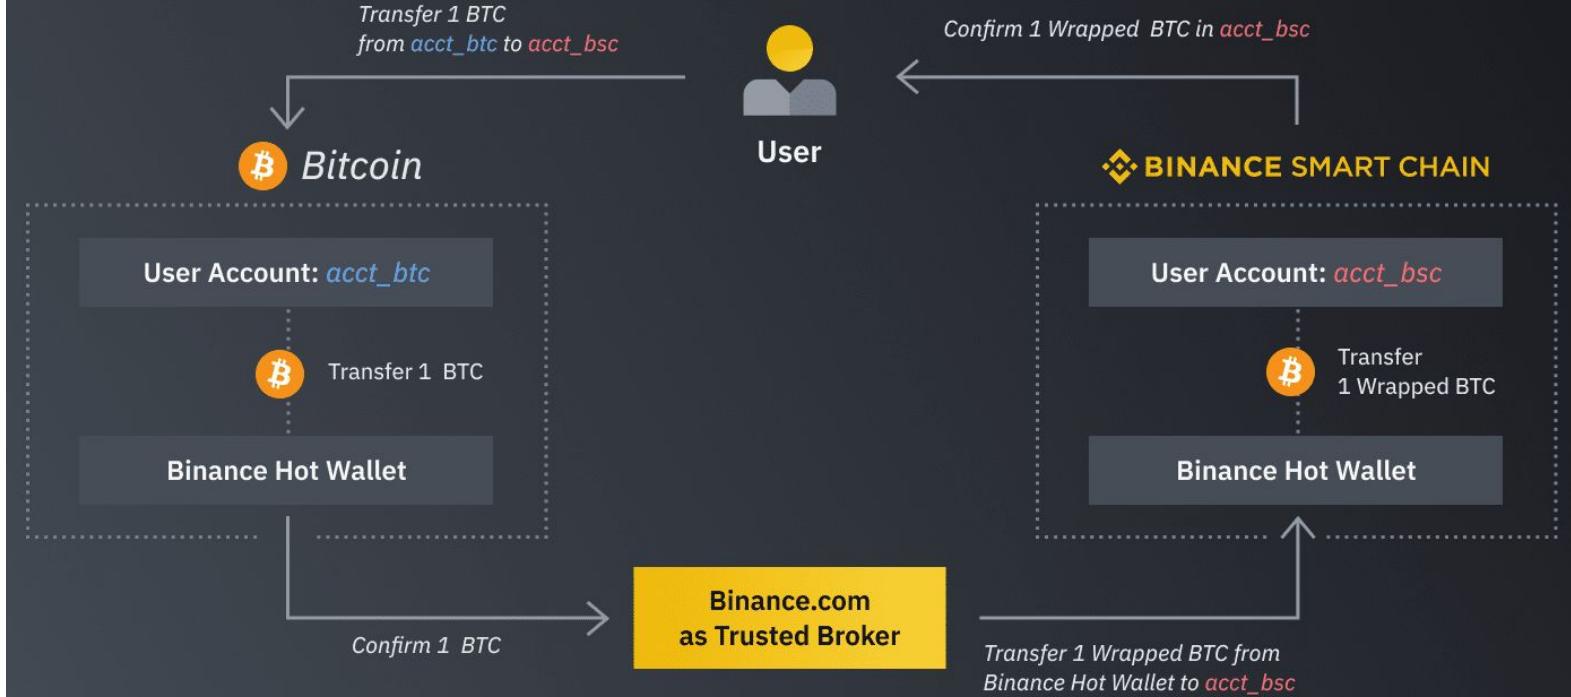

Introduction to Binance Smart Chain

- Launched by Binance in September 2020
- Parallel blockchain to Binance Chain
- Supports smart contracts and dApps
- EVM-compatible (Ethereum Virtual Machine)
- Designed for high performance and low fees
- High transaction speed (~3 second block time)
- Low transaction fees
- Ethereum compatibility
- Growing DeFi and NFT ecosystem
- Strong exchange backing (Binance)

Introduction to Binance Smart Chain

Binance Bridge

Binance Smart Chain - Ecosystem

- Dual-chain architecture: Binance Chain + BSC
- Binance Chain: Fast trading
- BSC: Smart contracts and DeFi
- Cross-chain compatibility
- Proof of Staked Authority (PoSA) consensus

Binance Smart Chain - Consensus Mechanism : PoSA

- Combination of Delegated Proof of Stake and Proof of Authori
- 21 active validators
- Validators selected based on staking and reputation
- Fast block confirmation
- Energy-efficient compared to PoW

Binance Smart Chain

BNB Token Utility in BSC

- Used for transaction fees (gas)
- Staking and validator participation
- Governance participation
- Utility in DeFi, NFTs, and gaming

BSC - Key Features

- EVM compatibility
- Smart contract support (Solidity)
- Low gas fees
- Cross-chain asset transfers
- High throughput

Binance Smart Chain - Usecases

- **Decentralized Finance (DeFi)**: BSC hosts a massive DeFi ecosystem, including PancakeSwap, Venus, and various yield farming protocols that thrive on low fees.
- **Non-Fungible Tokens (NFTs)**: Popular for minting and trading NFTs due to cost-effective transactions.
- **Blockchain Gaming (GameFi)**: High speed and low latency make it ideal for building decentralized games and in-game asset economies.
- **Token Launches (IDOs)**: Utilized for Initial DEX Offerings (IDOs) and token sales through platforms like Binance Launchpad.
- **Stablecoins and Assets**: Supports pegged tokens, bringing assets like BTC and ETH onto the BSC network.
- **Governance and Staking**: BNB holders can stake tokens to secure the network, act as validators, and participate in community governance

BSC Vs Ethereum

| Parameter | Binance Smart Chain (BSC) | Ethereum |
|---------------------------|----------------------------------|--|
| Launch Year | 2020 | 2015 |
| Founder | Binance | Vitalik Buterin |
| Native Token | BNB | ETH |
| Consensus Mechanism | Proof of Staked Authority (PoSA) | Proof of Stake (PoS) |
| Number of Validators | ~21 validators | Thousands of validators |
| Level of Decentralization | Moderate (more centralized) | High (highly decentralized) |
| Block Time | ~3 seconds | ~12 seconds |
| Transaction Speed (TPS) | Higher | Lower (Layer 1) |
| Gas Fees | Very low | Higher (depends on network congestion) |

BSC Vs Ethereum

| Parameter | Binance Smart Chain (BSC) | Ethereum |
|------------------------|--|---|
| Smart Contract Support | EVM-compatible | EVM-native |
| Security Level | Good but relatively lower due to validator concentration | Very high due to large validator network |
| Ecosystem Size | Growing DeFi ecosystem | Largest DeFi & NFT ecosystem |
| Popular dApps | PancakeSwap, Venus | Uniswap, Aave, OpenSea |
| Scalability Approach | High base-layer throughput | Layer 2 solutions (Arbitrum, Optimism, etc.) |
| Enterprise Adoption | Limited | Strong institutional and enterprise adoption |
| Best Suited For | Low-cost retail DeFi & high-volume transactions | Secure, large-scale, institutional-grade applications |

Since 1962

Binance Smart Chain

Advantages

- Scalability and speed
- Cost efficiency
- Developer-friendly (Solidity support)
- Large ecosystem support
- Strong liquidity via Binance

Challenges & Criticism

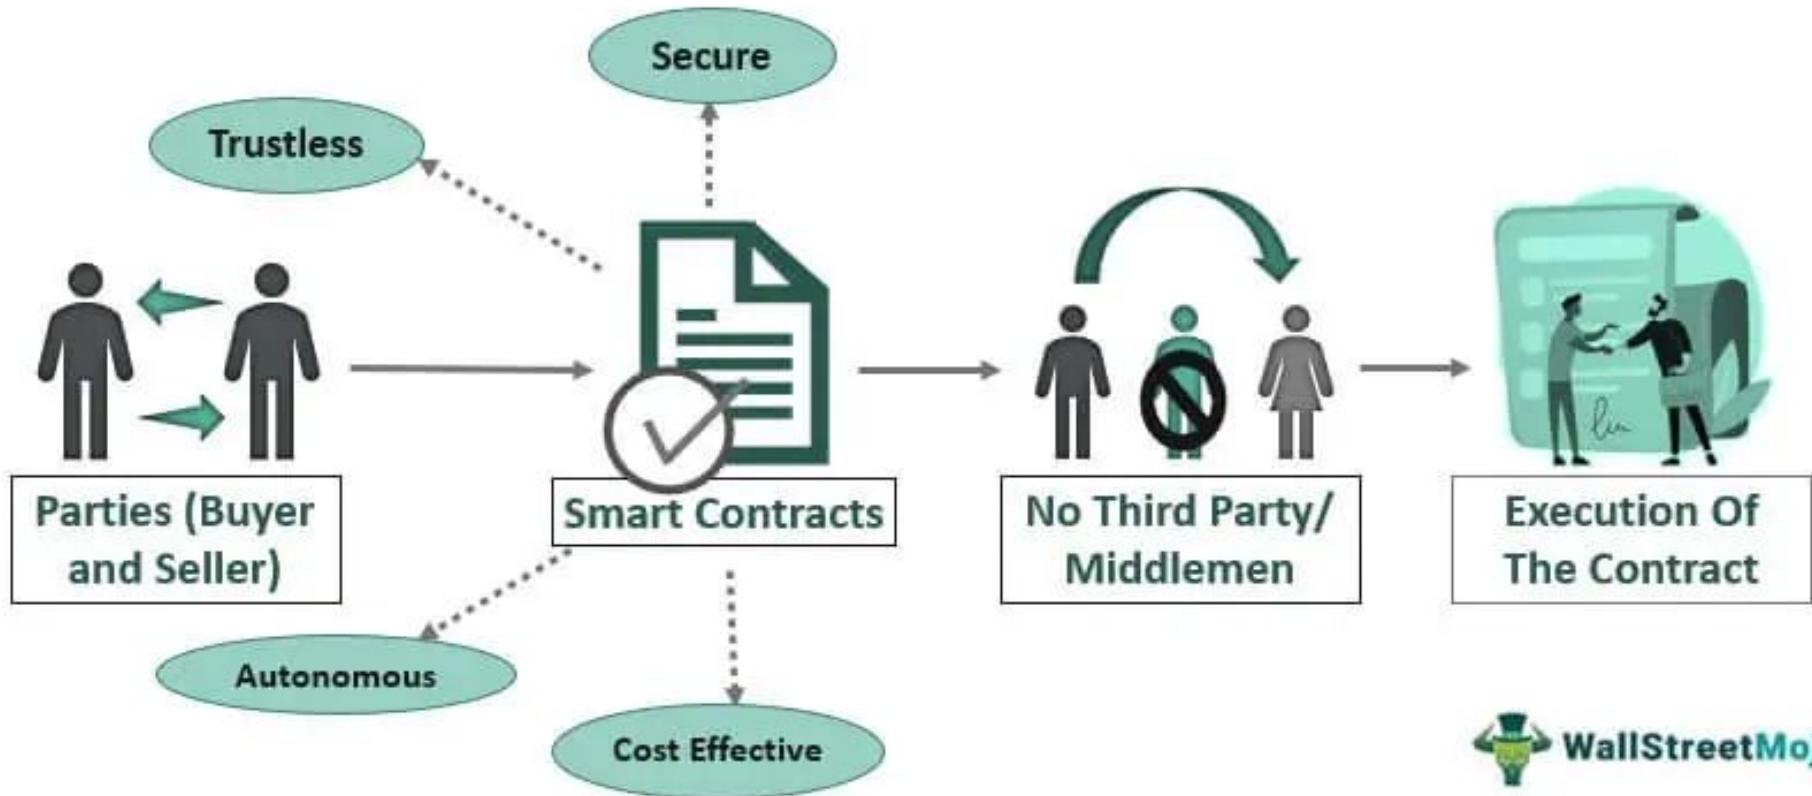

- Concerns about centralization
- Security vulnerabilities in DeFi projects
- Regulatory scrutiny
- Validator concentration risk

4. Smart Contract

- A **self-executing program** that automates the actions required in an agreement or contract. Once completed, the transactions are trackable and irreversible.
- Smart contracts **permit trusted transactions and agreements to be carried out among disparate, anonymous parties** without the need for a central authority, legal system, or external enforcement mechanism.
- **do not contain legal language**, terms, or agreements
- **Only code that executes actions when specified conditions** are met.
- Nick Szabo, an American computer scientist
 - invented a virtual currency called "**Bit Gold**" in 1998,
 - defined smart contracts as computerized transaction protocols that execute the terms of a contract

What is a Smart Contract ?

Features of Smart Contracts

1. **Distributed:** Everyone on the network is guaranteed to have a copy of all the conditions of the smart contract and they cannot be changed by one of the parties. A smart contract is replicated and distributed by all the nodes connected to the network.
2. **Deterministic:** Smart contracts can only perform functions for which they are designed only when the required conditions are met. The final outcome will not vary, no matter who executes the smart contract.
3. **Immutable:** Once deployed smart contract cannot be changed, it can only be removed as long as the functionality is implemented previously.
4. **Autonomy:** There is no third party involved. The contract is made by you and shared between the parties. No intermediaries are involved which minimizes bullying and grants full authority to the dealing parties. Also, the smart contract is maintained and executed by all the nodes on the network, thus removing all the controlling power from any one party's hand.
5. **Customizable:** Smart contracts have the ability for modification or we can say customization before being launched to do what the user wants it to do.
6. **Transparent:** Smart contracts are always stored on a public distributed ledger called blockchain due to which the code is visible to everyone, whether or not they are participants in the smart contract.
7. **Trustless:** These are not required by third parties to verify the integrity of the process or to check whether the required conditions are met.
8. **Self-verifying:** These are self-verifying due to automated possibilities.
9. **Self-enforcing:** These are self-enforcing when the conditions and rules are met at all stages.

Benefits of Smart Contracts

Autonomy

Accuracy

Transparency

High Speed

Data storage

Trustability

Cost Savings

Robust Backup

1. Smart Legal Contracts

- Legally enforceable
- Require the parties to fulfill their contractual obligations.
- Failure to do so may result in strict legal actions against them.

2. Decentralized Autonomous Organizations (DAO)

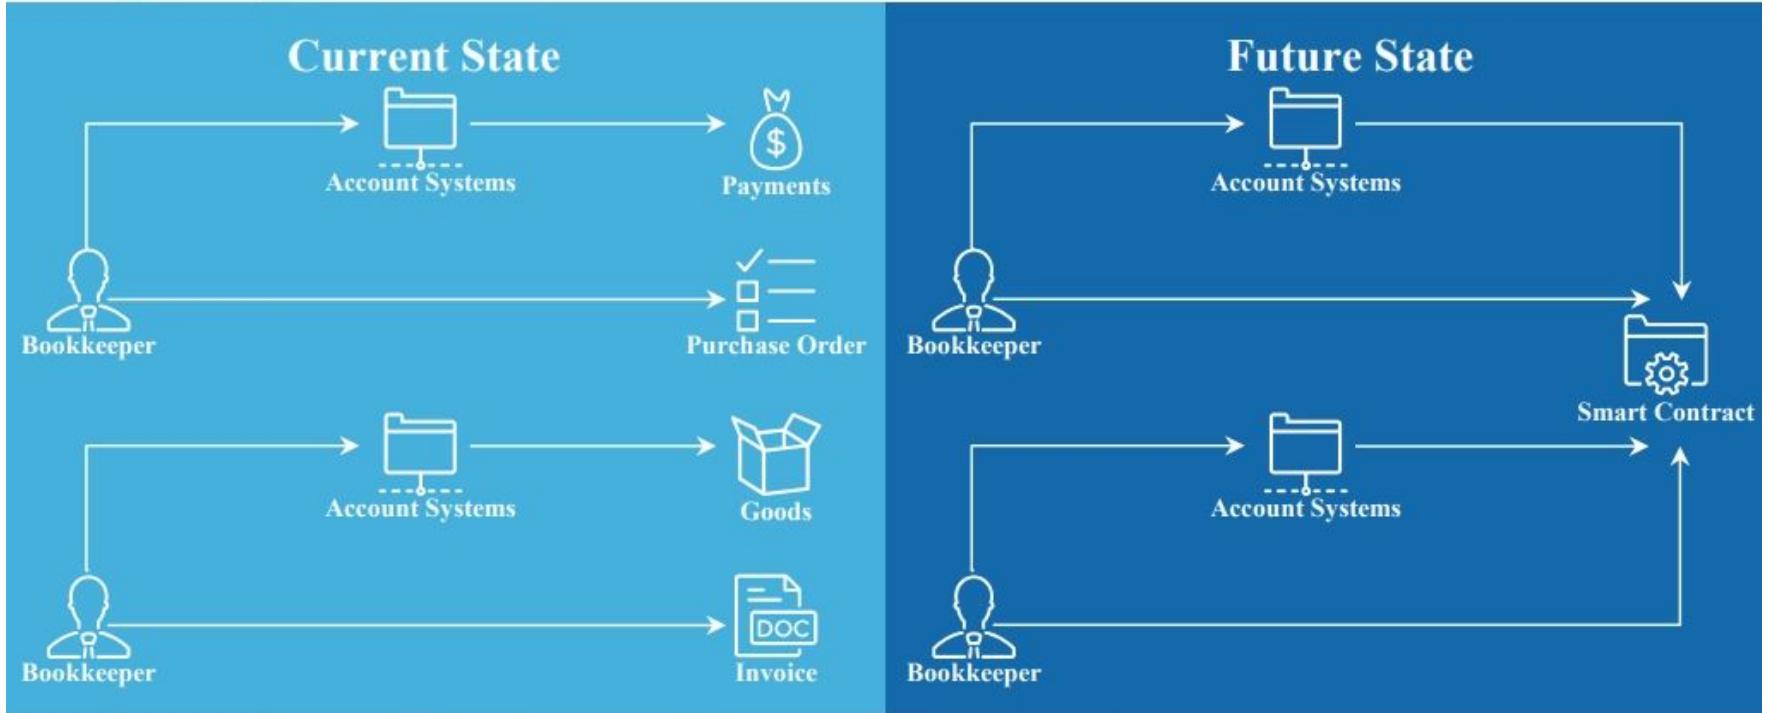

- These are blockchain communities that are bound to specific rules coded into blockchain contracts combined with governance mechanisms.
- Any action taken by the community members gets replaced by a self-enforcing code.

3. Application Logic Contracts (ALC)

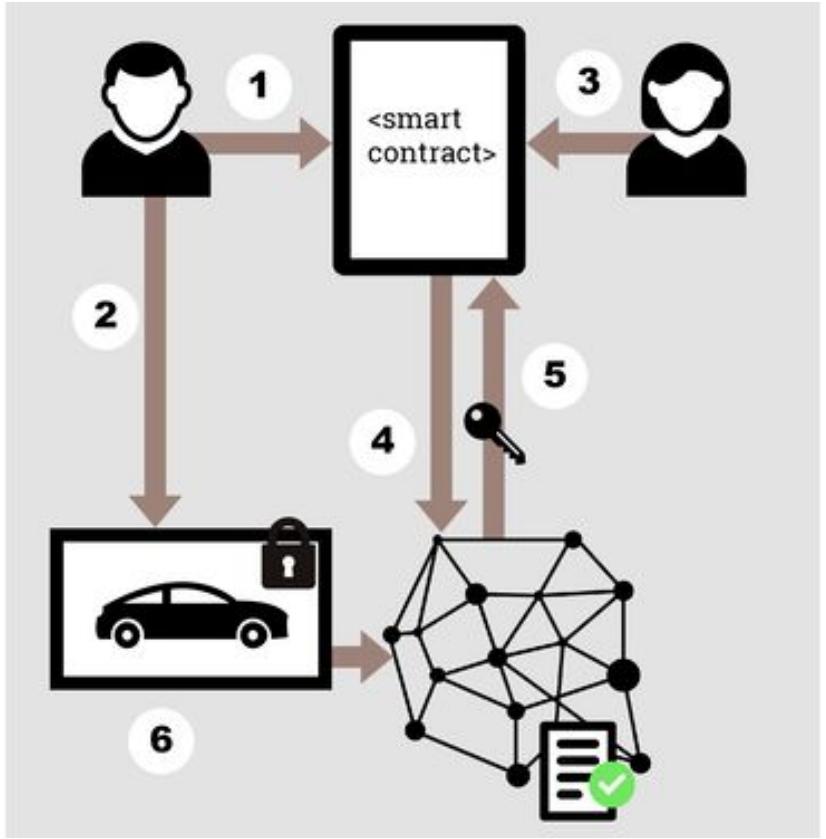

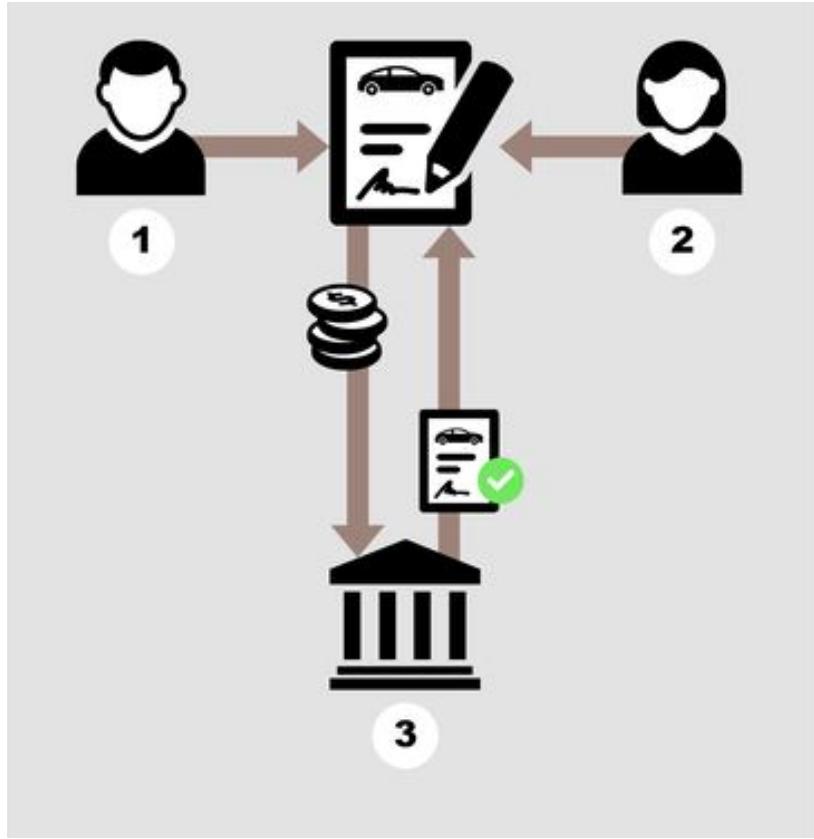

- contain an application-based code that remains in sync with other blockchain contracts.
- It enables communication across different devices, such as the merger of the Internet of Things with blockchain technology.

Future of Financial Reporting

Traditional Contracts Vs Smart Contracts

Traditional Contracts Vs Smart Contracts - Explained

Traditional Contracts

1. Bob would like to sell his car.
2. Alice would like to buy a car.
3. A third party (intermediary) enables the trust that is needed in order to transfer the ownership of the car. Mostly different intermediaries are needed: motor vehicle registration authority, notary, insurance company. All middlemen take fees.

Traditional Contracts Vs Smart Contracts - Explained

Smart Contracts

1. Bob would like to sell his car. He defines in a smart contract the conditions by which he will sell the car and signs the contract with his private key.
2. Bob leaves his car locked with a smart lock in his garage. The car has its own blockchain address and the smart lock is controlled by a smart contract.
3. Alice would like to buy a car. She finds Bobs car on an internet platform and signs the smart Bob's contract with her private key. She adds the agreed amount from her blockchain address to Bob's blockchain address.
4. As soon as the smart contract is executed the whole blockchain network will check if Bob is the real owner of the car and if Alice has enough money to buy the car.
5. If all peers in the blockchain network agree on the same state, it means that all conditions in the smart contract are met. The access code for the smart lock will be transferred to Alice and the blockchain address of the car will be registered to Alice. Bob will get the defined amount of money in his blockchain address.
6. Alice will be able to open the smart lock with her private key.

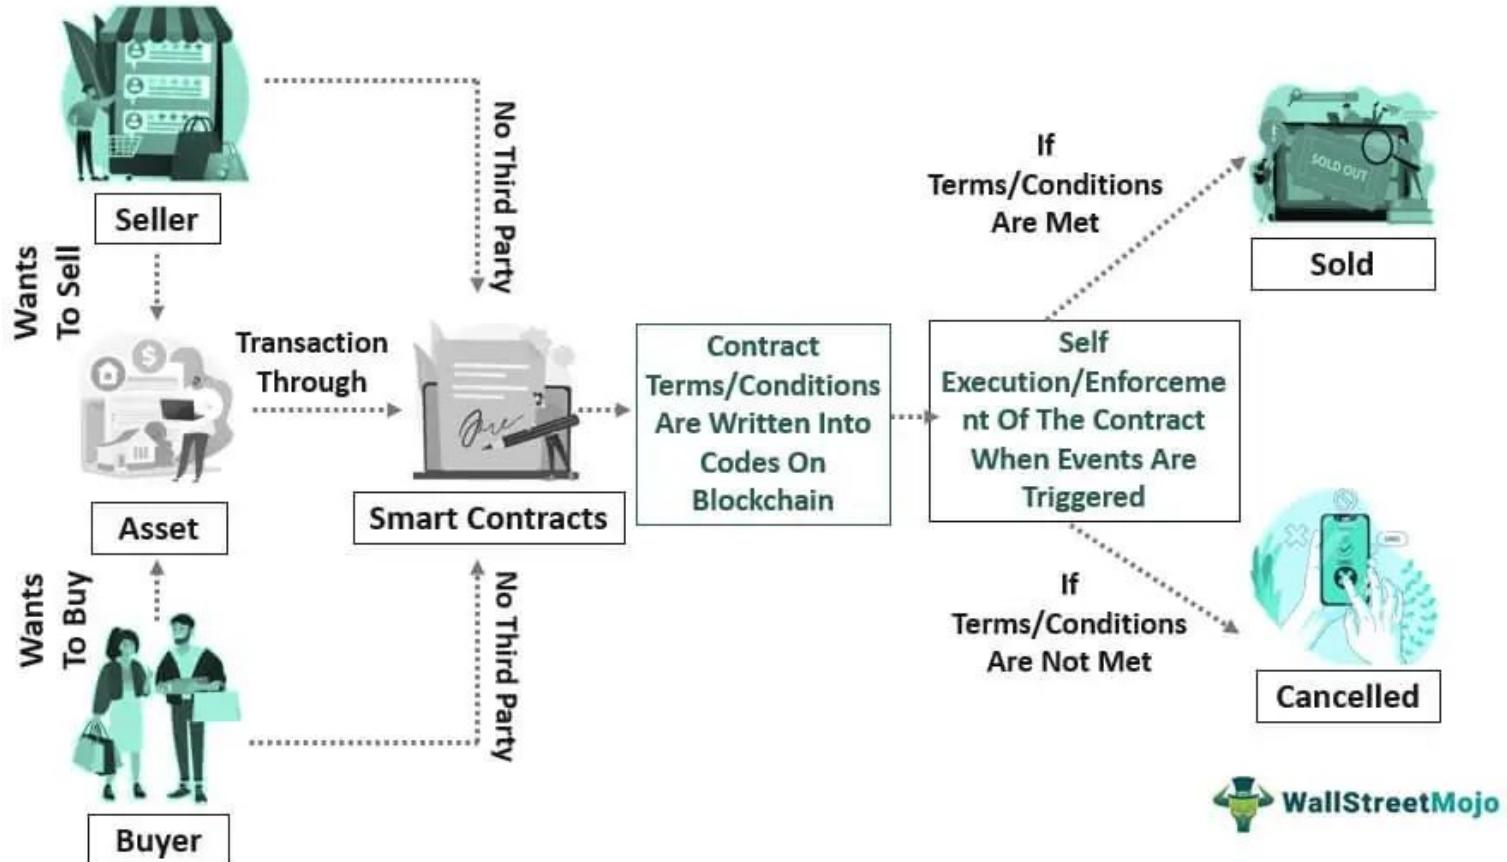

Future of Financial Reporting

| | Written contract | VS. | Smart contract |
|--|---|-----|--|
| Language/Code | Human language | | Machine computer code |
| Automation | All parts of the agreement | | Only transactions to be automated |
| Recording | Conditions can be written on a paper by the concerned parties | | Embedded into blockchain or another ledger |
| Modification of an internal state | Subject to interpretation | | Generally immutable |

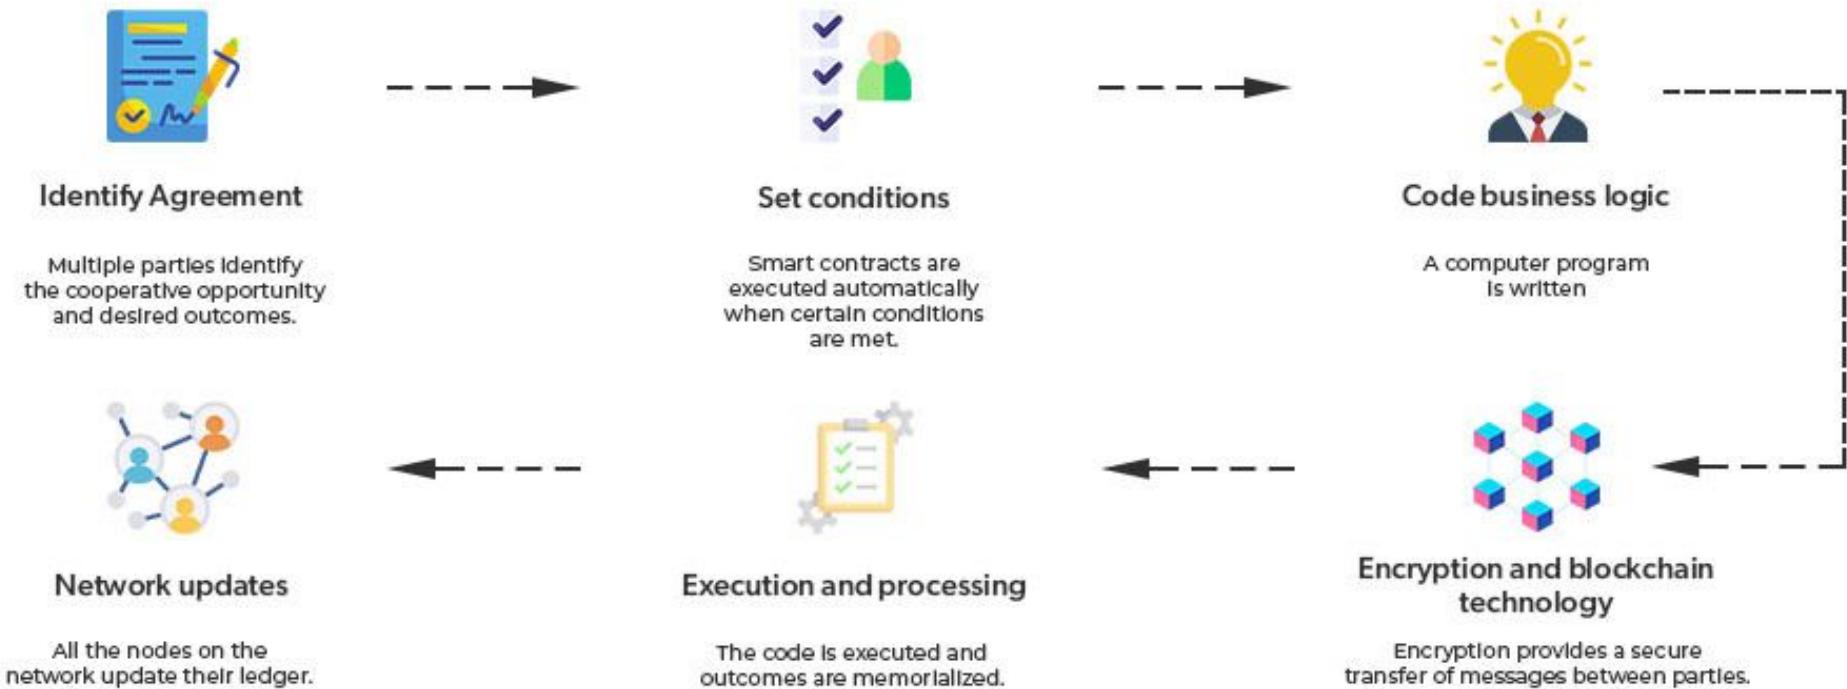

Smart Contract Functioning

 **WallStreetMojo**

How do smart contracts work ?

How do smart contracts work ?

1. **Identify Agreement:** Multiple parties identify the cooperative opportunity and desired outcomes and agreements could include business processes, asset swaps, etc.
2. **Set conditions:** Smart contracts could be initiated by parties themselves or when certain conditions are met like financial market indices, events like GPS locations, etc.
3. **Code business logic:** A computer program is written that will be executed automatically when the conditional parameters are met.
4. **Encryption and blockchain technology:** Encryption provides secure authentication and transfer of messages between parties relating to smart contracts.
5. **Execution and processing:** In blockchain iteration, whenever consensus is reached between the parties regarding authentication and verification then the code is executed and the outcomes are memorialized for compliance and verification.
6. **Network updates:** After smart contracts are executed, all the nodes on the network update their ledger to reflect the new state. Once the record is posted and verified on the blockchain network, it cannot be modified, it is in append mode only.

Steps involved in the Smart Contracts

Identify parties and establish the terms of the agreement

Define conditions for contract execution

Write smart contract code

Deploy contract to a blockchain platform

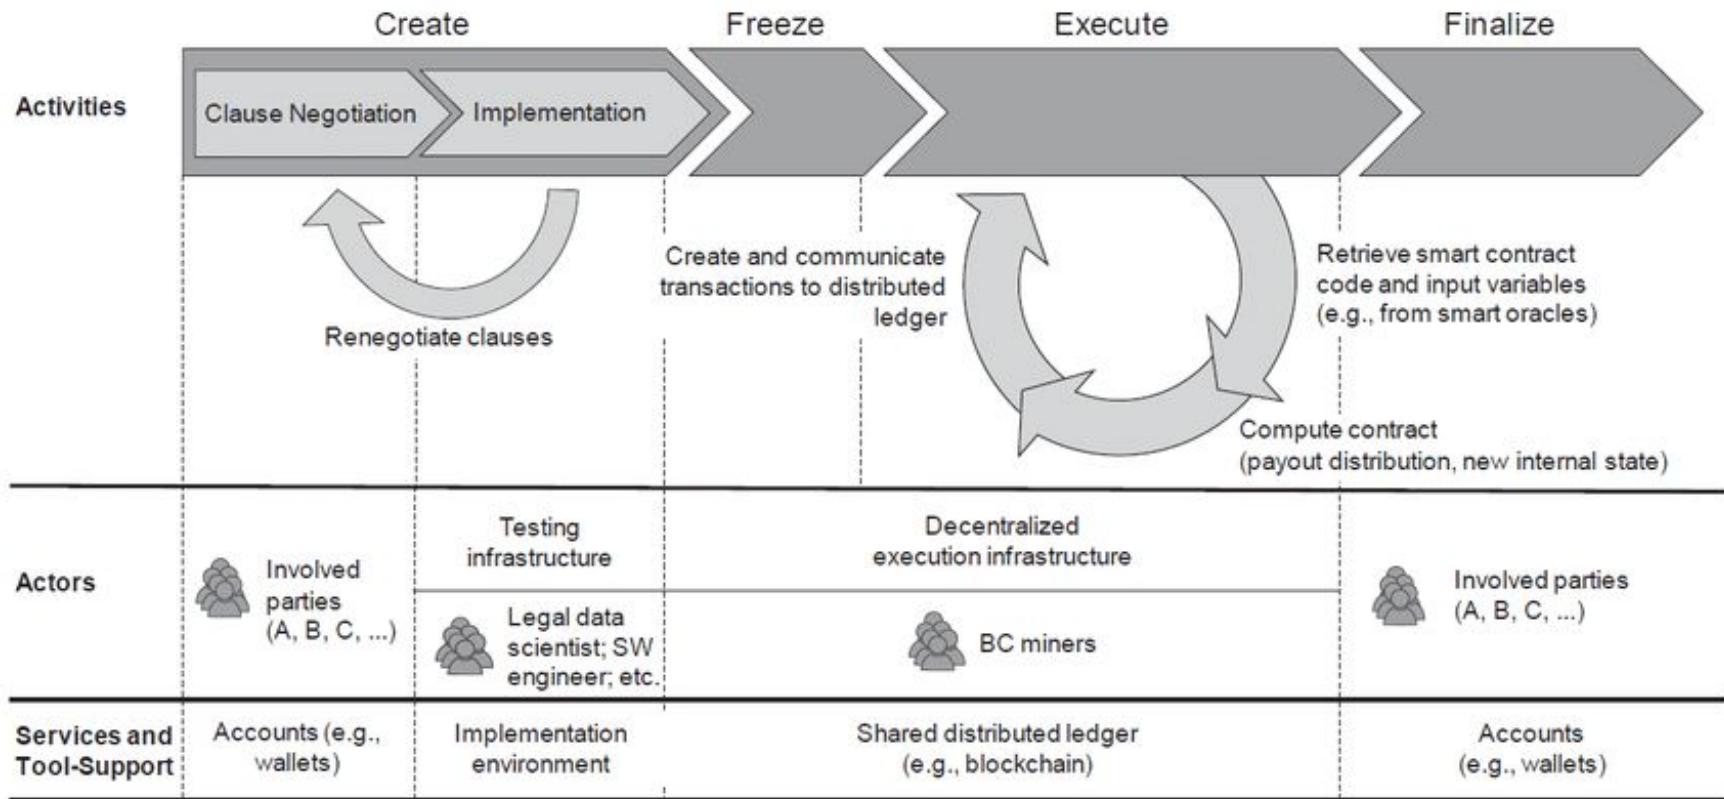

Trigger contract execution automatically

Record contract details on the blockchain ledger

Life Cycle of a Smart Contract

1. Creation Phase:

- consists of iterative contract negotiation and an implementation phase.
- First, the parties must agree on the broad content and goals of the contract.
- Similar to typical contract negotiations and can be conducted online or in person contracts
- During this phase, the following tasks are completed:
 1. Multiple-party bargaining.
 2. Design, implementation, and validation of smart

2. Freeze:

- The validation of transactions on a blockchain is performed by a network of computers known as nodes. The blockchain miners are these nodes.
- To prevent the ecosystem from being swamped with smart contracts, miners must be paid a tiny fee in exchange for this service.

3. Execution:

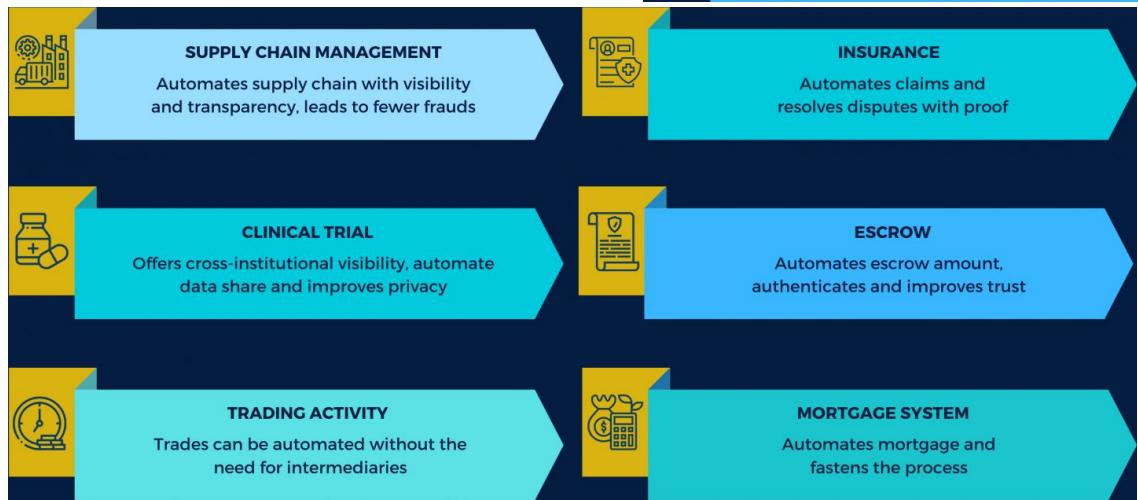

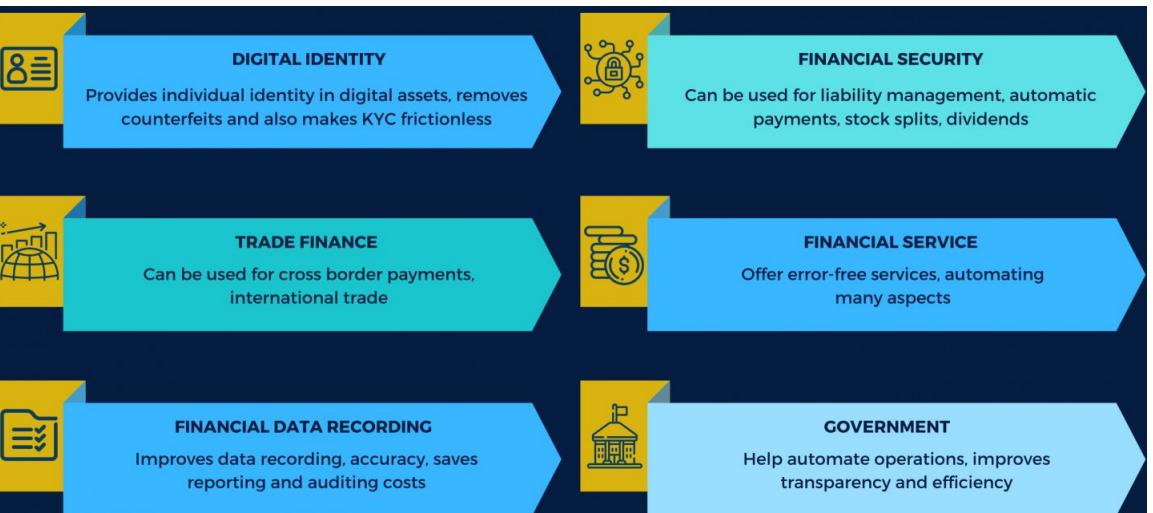

- Contracts placed on the distributed ledger are read by participating nodes.
- The authentication nodes validate the integrity of a smart contract,
- the code is performed by the smart contract interference engine (or by the compiler).
- When one party's inputs for execution are received in the form of coins (commitment to goods via coins), the interference engine **generates a transaction triggered by the met criterion**.
- The execution of the smart contract **results in a new set of transactions and a new state for the smart contract**.
- The **discoveries and new state information** are entered into the distributed ledger and validated using the consensus procedure.

4. Finalize:

- the resulting transactions and updated state information are recorded in the distributed ledger and confirmed via the consensus process.
- The previously pledged digital assets are transferred (assets are unfrozen), and the contract is signed to confirm all transactions.

Use cases of Smart Contracts

- Identity Data Protection
- Decentralized Identity Management
- Decentralized Access Control

Real Estate

- Improved Secure Transaction Process
- Eliminated Processing Fees and Commissions

Healthcare

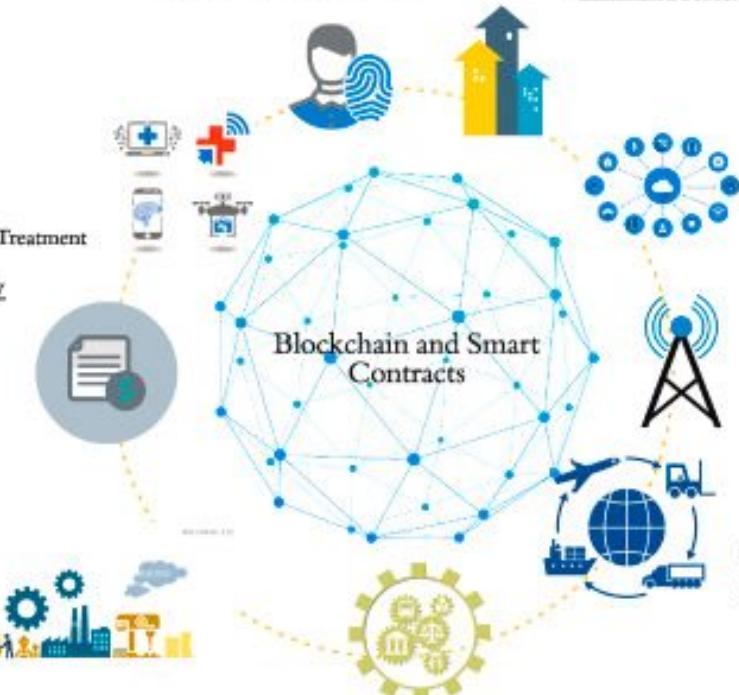

- Health Information Management
- Clinical Research Data Protection
- Automated Patient Monitoring and Treatment

Currency

- Currency
- Know Your Customer
- Escrow
- Insurance
- Lending
- Auditing
- Stock Trading

Cross Industry

- Energy Trading
- Waste Management
- Automotive Industry
- Additive Manufacturing

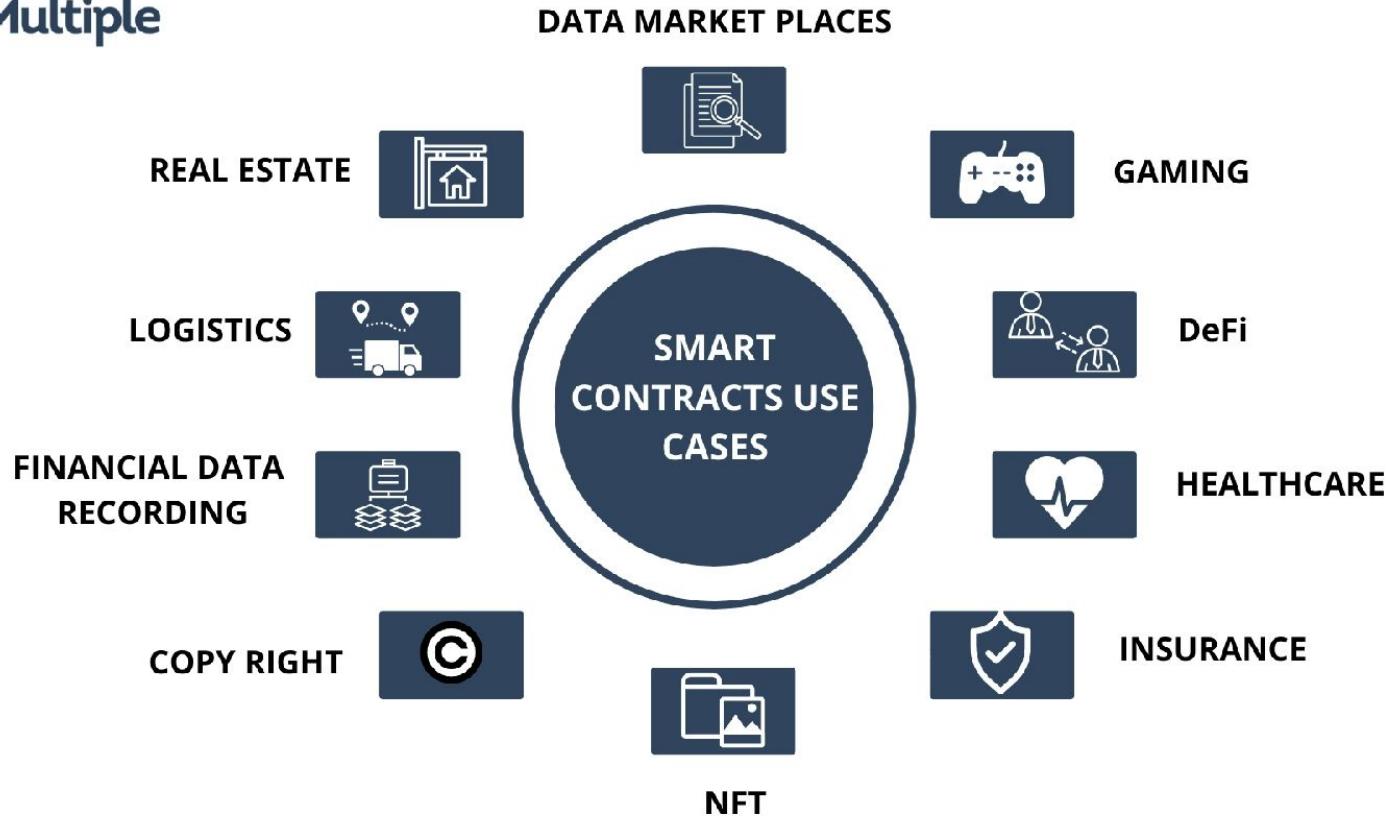

eGovernment/ Law

- Enforcement of Law by Smart Contracts
- Smart Contracts to Automate Contractual Agreements
- Smart Contracts for Public Services

Top 10 Use cases of Smart Contract 2023

Common Use cases of Smart Contract

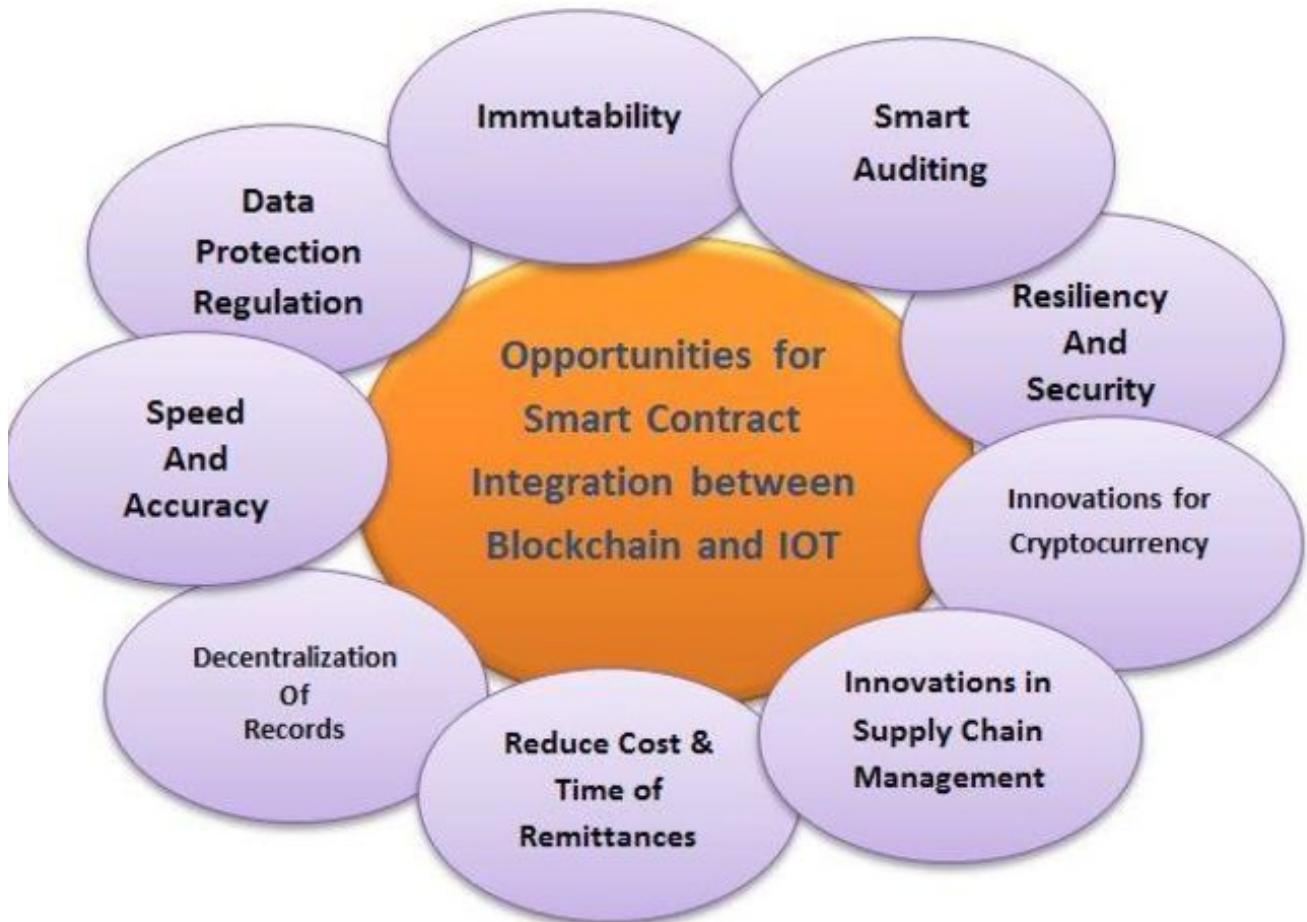

- **DeFi**

- Cryptocurrencies and smart contracts have allowed decentralized finance platforms to provide financial services without a need for a middleman.
- DeFi had a total value locked of [\\$94](#) billion by end of 2021.
- DeFi has evolved to be more than just peer-to-peer transactions.
- Smart contracts have enabled sophisticated transactions such as lending, borrowing, and derivative transactions on DeFi platforms.
- For example:
 - [AAVE](#) is a DeFi platform that allows borrowing and lending in different cryptocurrencies.
 - [Opyn](#) is a DeFi derivative trading platform that utilizes smart contracts for options trading.

- **NFTs**

- \$17 billion worth of [Non-fungible tokens \(NFTs\)](#) were traded in 2021, making it one of the most impactful smart contract use cases.
- Even though the market has cooled down in the 2nd quarter of 2022, NFTs have real-life [use cases](#) which can lead to long-term use of NFTs.
- Smart contracts have [enabled](#) the creation of non-fungible tokens (NFTs) by allocating ownership and managing the transferability of NFTs. These contracts can also be modified to include additional features such as royalty payments and access rights to a platform or software.

Smart Contract Opportunities

1. **Trust and Transparency:** Smart contracts operate on decentralized blockchain networks, ensuring trust and transparency in transactions. Parties involved can rely on the code's execution rather than trusting a centralized authority.
2. **Reduced Intermediaries:** By automating contract execution, smart contracts eliminate the need for intermediaries like banks, lawyers, or notaries, reducing costs and delays associated with traditional contracts.
3. **Efficiency:** Smart contracts execute automatically once predefined conditions are met. This reduces manual errors, speeds up processes, and lowers administrative costs.
4. **Security:** Blockchain technology provides a high level of security through encryption and consensus mechanisms. Once data is on the blockchain, it is challenging to alter, enhancing data integrity.
5. **Global Reach:** Smart contracts can be accessed and executed globally, enabling businesses to interact with international partners and customers seamlessly.
6. **Immutable Records:** Transactions recorded on a blockchain are tamper-resistant and cannot be altered once confirmed, ensuring a reliable and permanent record

Smart Contract Challenges

1. **Coding Errors:** Smart contracts are only as good as the code written to create them. Coding errors or vulnerabilities can lead to significant financial losses or breaches of privacy. The code must be thoroughly audited and tested.
2. **Regulatory Uncertainty:** The legal and regulatory framework for smart contracts varies by jurisdiction. The lack of clarity in some areas can lead to legal challenges or compliance issues.
3. **Irreversible Transactions:** Once a smart contract is deployed, its actions are irreversible. If there's a mistake or dispute, it can be challenging to resolve without external intervention.
4. **Oracles and External Data:** Smart contracts often rely on external data sources (oracles) to trigger actions. If these sources provide incorrect or manipulated data, it can lead to undesirable outcomes.
5. **Scalability:** Blockchain networks, especially Ethereum, face scalability challenges, resulting in slow transaction times and high fees during periods of high demand.
6. **Privacy Concerns:** While blockchain provides transparency, it may not be suitable for contracts that require complete privacy or confidentiality.
7. **Human Element:** Smart contracts can't account for all real-world scenarios. Human intervention may still be needed for complex negotiations or unforeseen circumstances.
8. **Upgrades and Forks:** Blockchain networks can undergo upgrades or forks, potentially impacting the functionality or compatibility of smart contracts.
9. **Cost of Deployment:** Deploying smart contracts on some blockchain networks can be costly due to gas fees (transaction costs) and development expenses.

Blockchain based Smart Contract Integration Platforms

| Platform | Blockchain | Smart Contract Language | Consensus Protocol | Cryptocurrency | System Complexity | Scalability |
|---------------------------|------------------|--------------------------|--------------------|----------------|-------------------|--------------------------------|
| BitCoin | Public & Private | IVY for Bitcoin Language | PoW | BTC | Medium | Block size 3-7 Tx/Sec |
| Ethereum | Public & Private | Solidity | PoS | Ether (ETH) | High | Block size 5-20 Tx/Sec |
| HyperLedger Fabric | Private | Java, Node.js and Go | PBFT/SIEVE | None | High | Block size 100-3000 Tx/Sec |
| NEM | Public | Java and Node.js | PoI | XEM | Medium | Block size 1,000-10,000 Tx/Sec |
| Stellar | Public | Stellar SDK & Go | PBFT / FBA | Lumens (XLM) | High | Block size 1,000-1,500 Tx/Sec |
| Waves | Public | RIDE | LPoS | WAVES | Medium | Block size 100 Tx/Sec |
| Lisk | Public | Lisk JScript | DPoS | LSK | Medium | Block size 25Tx/Sec |
| NXT | Public | TC Script | PoS | NXT | Medium | Block size 5-20 Tx/Sec |
| Monax | Private | Monax SDK and Solidity | PoS | MultiAsset | High | - |
| Qtum | Public | QSCL and Solidity | PoS | QTUM | Medium | Block size 70-140Tx/Sec |

Smart Contracts by Complexity Level

Use case examples

Digital value exchange

A family member sends some bitcoin to another family member

Smart right and obligation

Consumer buys a digital content stream

Basic smart contract

Landlord remotely locks nonpaying tenant out of apartment

Multiparty smart contract

Seller lends buyer funds to buy a house

Distributed autonomous business unit

Unit of a corporation issues its own bonds, and buyers monitor payments via a shared ledger

Distributed autonomous organization

Self-driving trucks make P2P deliveries, pay local toll road fees, and buy local electricity

Distributed autonomous government

Settlers of a previously uninhabited area code their own self-enforcing government services

Distributed autonomous society

Simple

Complex

5. Overview of Decentralized Applications (DApps)

- A software application that operates on a decentralized network, typically using blockchain technology.
- Compared to traditional applications that rely on centralized servers, Dapps leverage the security, transparency, and trustlessness of blockchain to function.
- Salient Features of DApps

1. Decentralization:

- Dapps run on a decentralized network of computers, often referred to as a blockchain.
- This network is distributed across many nodes, making it resistant to single points of failure and censorship.

2. Smart Contracts:

- Dapps typically use smart contracts, which are self-executing contracts with the terms of the agreement directly written into code.
- Smart contracts automatically execute actions when specific conditions are met, without the need for intermediaries.

3. Transparency:

- All transactions and actions within a Dapp are recorded on a public ledger (the blockchain).
- This transparency ensures that anyone can verify transactions and data, enhancing trust in the application.

Introduction to Dapp (Decentralized Application)

4. Security:

- Blockchain technology, with its cryptographic techniques, provides a high level of security.
- Transactions are immutable, meaning once recorded on the blockchain, they cannot be altered.
- This makes Dapps resilient to fraud and hacking.

5. Trustlessness:

- Dapps aim to operate without relying on a central authority or intermediary.
- Users can interact with the application and each other directly without needing to trust a third party.

6. Token Economy:

- Many Dapps have their own native tokens or use established cryptocurrencies like Ethereum's Ether.
- These tokens can be used for various purposes within the application, such as paying for services, participating in governance, or earning rewards.

7. Use Cases:

- Dapps have a wide range of use cases, including decentralized finance (DeFi), non-fungible tokens (NFTs), supply chain management, voting systems, gaming, and more.
- Each Dapp is designed to solve specific problems or provide new functionalities in a decentralized manner.

Introduction to Dapp (Decentralized Application)

8. User Interface:

- Dapps often have user interfaces (UIs) similar to traditional apps or websites, making them accessible to a broader user base.
- Users may not even be aware that they are interacting with blockchain technology.

9. Challenges:

- While Dapps offer numerous advantages, they also face challenges, including scalability issues, user adoption barriers, and regulatory compliance.
- These challenges are actively being addressed by the blockchain community.

10. Development:

- Building a Dapp typically involves programming smart contracts using languages like Solidity (for Ethereum) and developing a frontend interface.
- Popular Dapp development frameworks like Truffle and web3.js make the development process more accessible.

1. Ethereum blockchain:

- Securely executes and verifies application code, called smart contracts.
- DApps use the Ethereum blockchain for data storage.

2. Smart Contracts:

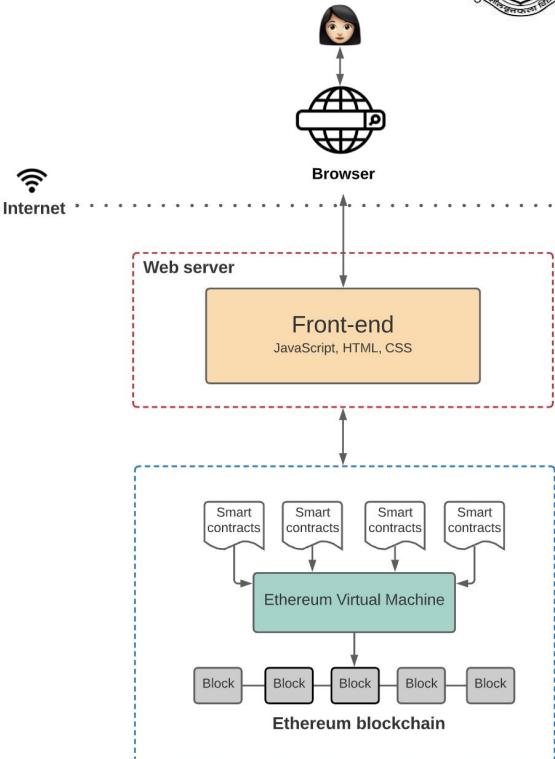

- DApps use smart contracts to define the state changes happening on the blockchain.
- A smart contract is a collection of code and data that resides at a specific address on the Ethereum Blockchain and runs on the Ethereum blockchain.

3. Ethereum Virtual Machine(EVM):

- Global virtual computer that executes the logic defined in the smart contracts and processes the state changes that happen on this Ethereum network.

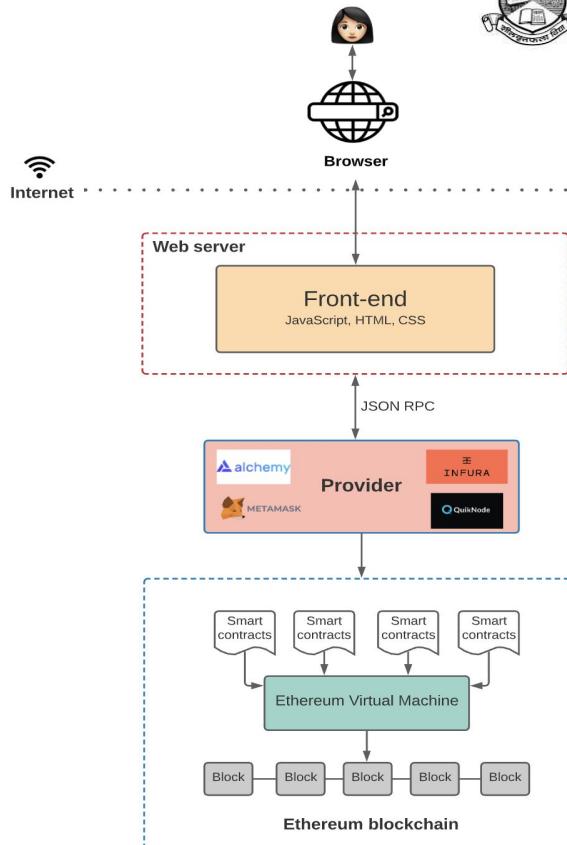

4. Front-end:

- The part of the DApps, that users can see and interact with such as the graphical user interface(GUI),
- Communicates with the application logic defined in smart contracts.

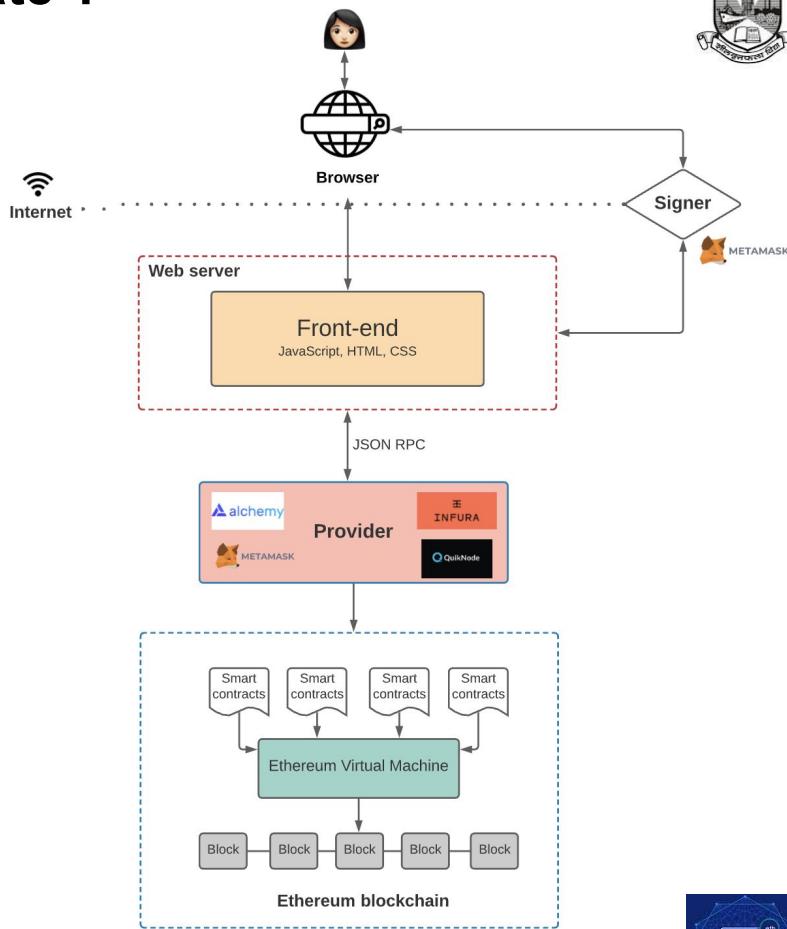

DApp - How Frontend Code Communicate ?

- When we need to interact with the data and code on a blockchain, we need to interact with one of these nodes.
- As any node can broadcast a request for a transaction to be executed on the EVM.
- A miner will then execute the transaction and propagate the resulting state change to the rest of the network.
- There are two ways to broadcast a new transaction:
 1. Set up your own node which runs the Ethereum blockchain software
 2. Use nodes provided by third-party services like [Infura](#), [Alchemy](#), and [Quicknode](#)
- Every Ethereum client (i.e. provider) implements a JSON-RPC specification. This ensures that there's a uniform set of methods when frontend applications want to interact with the blockchain.

DApp - How Frontend Code Communicate ?

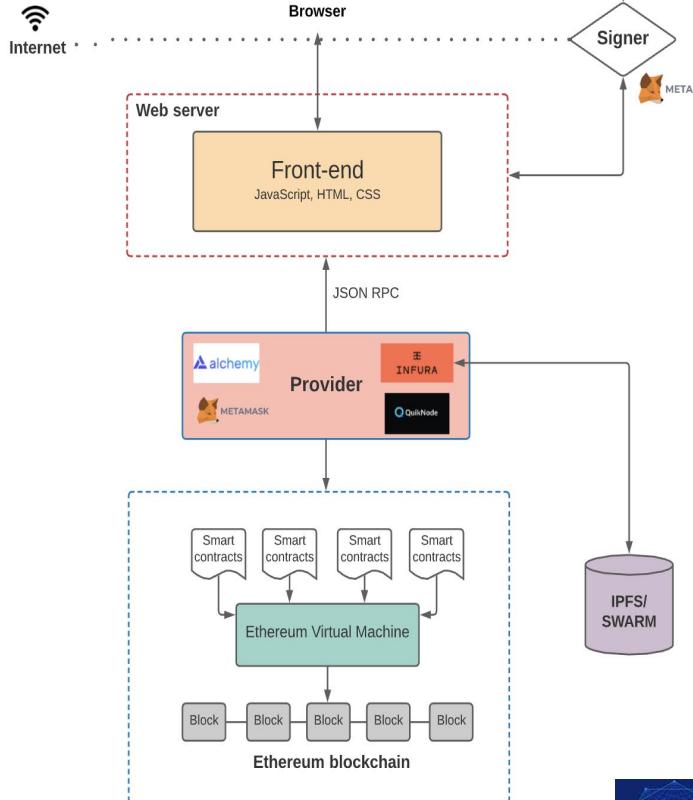

- When a user wants to publish a new post onto the chain, our DApp would ask the user to “sign” the transaction using their private key — only then would the DApp relay the transaction to the blockchain.
- Otherwise, the nodes wouldn’t accept the transaction.
- This “signing” of transactions is where [Metamask](#) typically comes in.

DApp - Storage on the Blockchain

- Storing everything on the blockchain gets really expensive.
- Users to pay extra for using your DApp every time their transaction requires adding a new state is not the best user experience.
- One way to combat this is to **use a decentralized off-chain storage solution**, like [IPFS](#) or [Swarm](#).
- IPFS : Distributed file system for storing and accessing data.
 - distributes and stores the data in a peer-to-peer network.
 - Has an incentive layer known as “Filecoin.” This layer incentivizes nodes around the world to store and retrieve this data.
 - IPFS providers
 - **Infura** (which provides you with an IPFS node) or
 - Pinata (“pin” your files to IPFS and take the IPFS hash and store that on the blockchain).
- **Swarm** : A decentralized storage network,
 - **Difference :** Swarm’s incentive system is built-in and enforced through smart contracts on the Ethereum blockchain for storing and retrieving data.

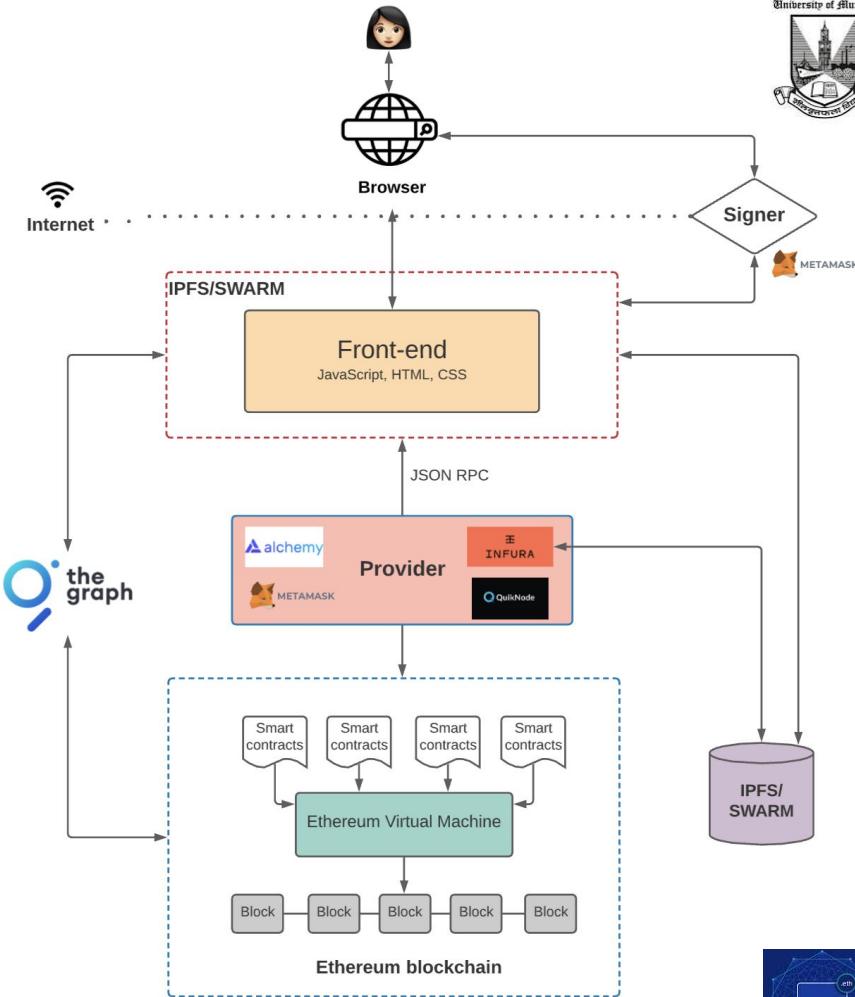

DApp Querying the Blockchain

1. Smart Contract Events :

- Use the Web3.js library to query and listen for smart contract events.
- Here, we need to listen to specific events and specify a callback every time the event is fired.
- using callbacks to handle various UI logic gets very complex
- Issue: when you deploy a smart contract and later realize you need an event emitted that you didn't originally include.

2. The Graph

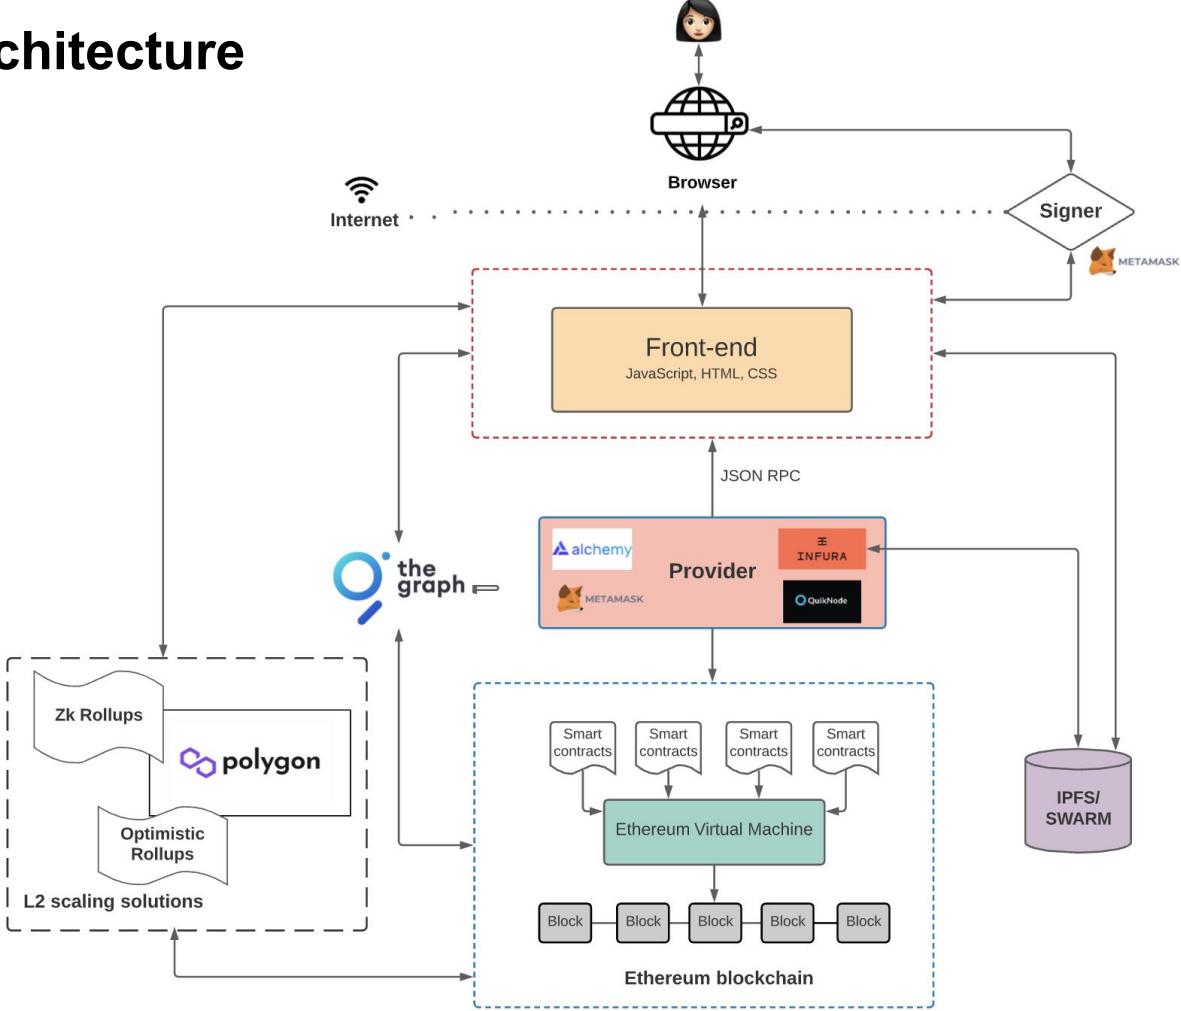

- An off-chain indexing solution that makes it easier to query data on the Ethereum blockchain.
- Allows to define which smart contracts to index, which events and function calls to listen to, and how to transform incoming events into entities that the frontend logic can consume.
- It uses **GraphQL** as a query language,
- By indexing blockchain data, The Graph lets us query on-chain data in our application logic with low latency

Overall DApp Architecture

Addressing

- Storage,
- Querying
- Scalability

6. Token Standards

WHAT ARE ERC STANDARDS?

Ethereum Request for Comments (ERC) is a document that smart contract programmers are using in the Ethereum blockchain platform to write. These are rules that the Ethereum-based tokens must comply with.

CREATION PROCESS

DIFFERENT ETHEREUM REQUEST FOR COMMENTS

- Most popular token standard.
- Used in most of the ICOs.
- Fungible token standard.
- Allows the implementation of standard API within a smart contract.

ERC 20

- A standard for a method, instead of tokens.
- Covers how interfaces are identified.
- States how any contract can publish the interfaces after the implementation.
- States how to detect when a contract implements ERC-165.
- Covers the way to detect when a smart contract uses any given interface.

ERC 165

- A standard for non-fungible tokens.
- Allows the implementation of standard API for NFTs within a smart contract.
- Offers functionality to transfer and track NFTs.

ERC 721

- Reduces friction in crypto transactions.
- Not in use, still in EIP phase.
- Gets rid of the double transaction verification of ERC 20.
- Lowers transaction overhead.
- Allows users to reject incoming tokens from a blacklisted address.

ERC 777

- Prevents accidental burns of tokens, a bug in ERC 20.
- Developers can either accept or decline tokens arriving at their smart contract addresses.
- Rejected transactions will fail but won't burn the tokens.
- Not in use, still in EIP phase.

ERC 223

- An extension to ERC 20 standard
- Uses two functions -'increaseSupply', and 'decreaseSupply'
- Can increase or decrease the token supply.
- Not in use, still in EIP phase.

ERC 621

- An extension of ERC 20.
- Wallets and exchanges can reuse tokens.
- Token holders can transfer token while also approving a 3rd party to spend it.
- Not in use, still in EIP phase.

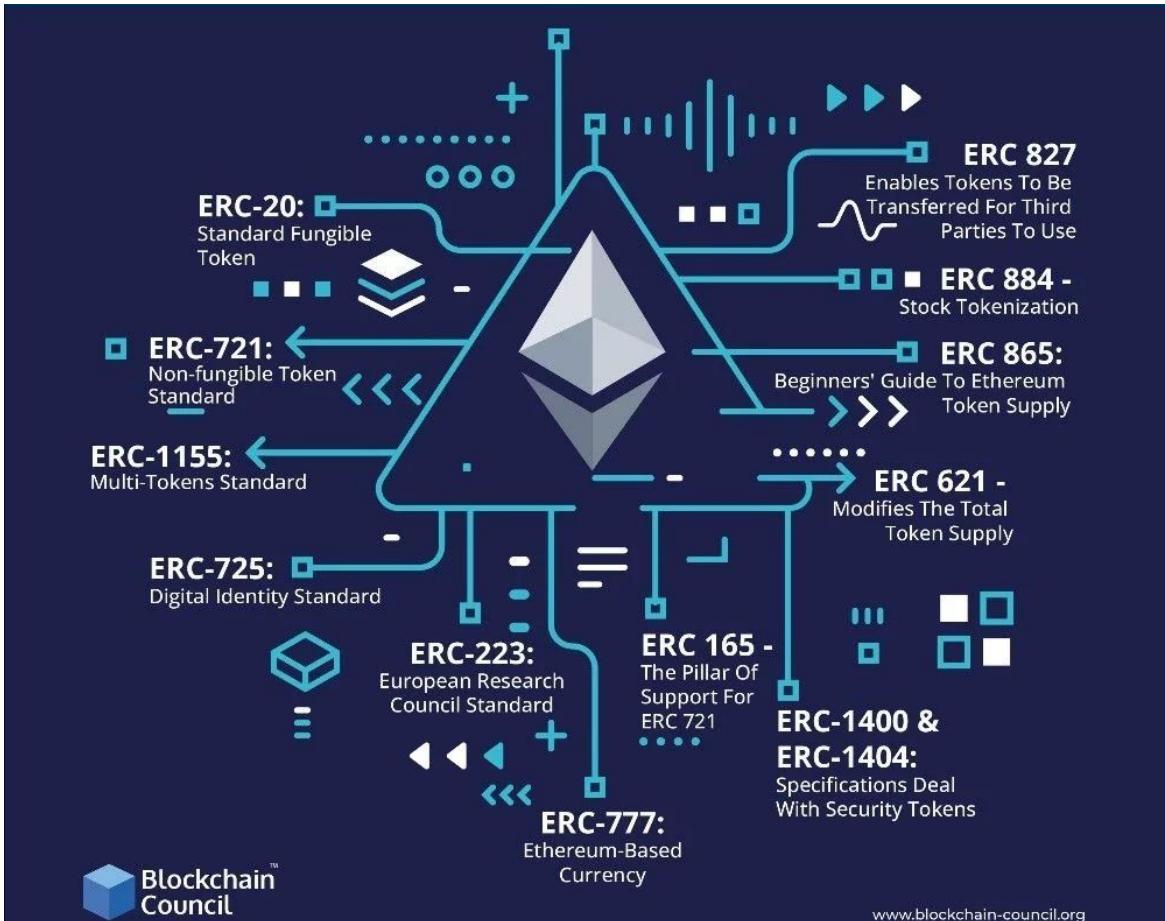

ERC 827

- Allows companies to use blockchain to maintain share registries.
- Identity verification and mandatory whitelisting of token holders.
- Only whole value of tokens, i.e., no partial value.
- Recording of information regulators mandate.
- Not in use, still in EIP phase.

ERC 884

ERC Token Standards List

Ethereum Token Standards

ERC - 20

Fungible Tokens

Most basic token standard, used to create interchangeable tokens

ERC - 721

Non-Fungible Tokens

Basic NFT standard, used to create unique tokens, distinguishable from others in the same collection

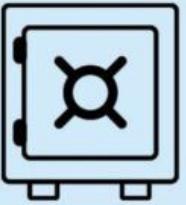

ERC - 1155

Multi-Token Standard

A single interface that manages any combination of multiple token types (fungible, non-fungible, etc).

ERC - 4626

Tokenized Vault Standard

A standard that represents a yield-bearing vault; extending ERC-20 to include deposit, redeem, etc

Trade-able virtual currencies
Governance/voting tokens
Staking tokens

Collectable art
Digital items and property
Tickets (events, seats, lottery)

Alternate to ERC-20 and ERC-721
Video game items
Memorabilia

Lending markets
Interest bearing tokens
Aggregators

Twitter: @SalomonCrunto

ERC20

ERC20 Token

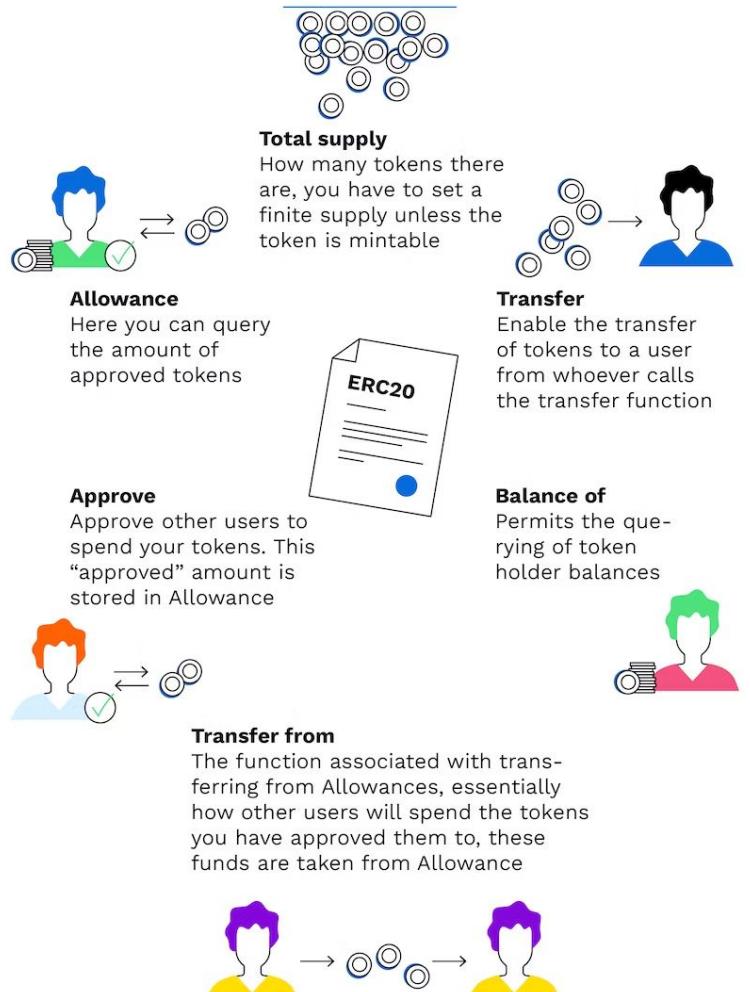

- ERC-20 is the **technical standard for fungible tokens created using the Ethereum blockchain**.
- A **fungible token is interchangeable with another token**—where the well-known non-fungible tokens (NFTs) are not interchangeable.
- ERC-20 allows developers **to create smart-contract-enabled tokens that can be used with other products and services**.
- These **tokens are a representation of an asset, right, ownership, access, cryptocurrency, or anything else that is not unique in and of itself but can be transferred**.
- A **list of functions and events** that must be implemented into a token for it to be considered ERC-20 compliant.
 - **functions describe what must be included in the smart-contract-enabled token**,
 - **events describe an action**.
- ERC-20 guides the creation of new tokens on the Ethereum blockchain so that they are interchangeable with other smart contract tokens.

ERC20 Token Functions

- TotalSupply:** The total number of tokens that will ever be issued
- BalanceOf:** The account balance of a token owner's account
- Transfer:** Automatically executes transfers of a specified number of tokens to a specified address for transactions using the token
- TransferFrom:** Automatically executes transfers of a specified number of tokens from a specified address using the token
- Approve:** Allows a spender to withdraw a set number of tokens from a specified account, up to a specific amount
- Allowance:** Returns a set number of tokens from a spender to the owner

ERC20 Token

The events that must be included in the token are:

1. **Transfer:** An event triggered when a transfer is successful
2. **Approval:** A log of an approved event (an event)

The following functions are optional and are not required to be included, but they enhance the token's usability:

1. Token's name (optional)
2. Its symbol (optional)
3. Decimal points to use (optional)

ERC20 Token

What is the significance of ERC-20 tokens?

ERC-20 tokens have become the standard for creating new tokens on the Ethereum Blockchain. This standardization makes it easier for developers to create new tokens and for users to interact with them, as they all follow the same set of rules.

Additionally, ERC-20 tokens have enabled the creation of decentralized applications (dApps) on the Ethereum network, which has the potential to revolutionize industries.

What are the risks associated with ERC-20 tokens?

Like all cryptocurrencies, ERC-20 tokens are volatile and their value can fluctuate rapidly. Additionally, there is a risk of fraud, scams, and theft. It's important to do your research and be cautious when investing in ERC-20 tokens or any other cryptocurrency.

ERC20 Token

How do ERC-20 tokens differ from other cryptocurrencies?

ERC-20 tokens are built on the Ethereum Blockchain and follow a standardized set of rules and guidelines. This makes it easier for developers to create new tokens and for users to interact with them. Other cryptocurrencies may have different rules and guidelines, making them more complex to work with.

How can I use ERC-20 tokens?

- ERC-20 tokens can be used for a variety of purposes, including investment, trading, and participating in decentralized applications.
- Some ERC-20 tokens can also be used for purchasing goods and services, although this is less common.

ERC20 Token

Popular Digital currencies use the ERC-20 standard.

- [Tether USD](#) (USDT)
- [USD Coin](#) (USDC)
- [Shiba Inu](#) (SHIB)
- Binance USD (BUSD)
- [BNB](#) (BNB)
- DAI Stablecoin (DAI)
- [HEX \(HEX\)](#)
- Bitfinex LEO (LEO)
- MAKER (MKR)

ERC20 Token - Advantages

1. **Interoperability:** ERC-20 tokens adhere to a standardized set of rules, making them compatible with a wide range of wallets, exchanges, and applications. This interoperability fosters easy integration and widespread use across different platforms.
2. **Ease of Development:** Creating ERC-20 tokens is relatively straightforward due to the well-defined standard. This simplicity has lowered the barrier for developers to create their own tokens and launch initial coin offerings (ICOs) or token sales.
3. **Widespread Adoption:** The ERC-20 standard has gained widespread adoption within the Ethereum ecosystem. Many tokens, including some of the most well-known cryptocurrencies and utility tokens, are based on the ERC-20 standard.
4. **Liquidity and Trading:** ERC-20 tokens can be easily traded on various decentralized and centralized exchanges. Their widespread availability has contributed to liquidity and trading opportunities for token holders.
5. **Token Integration:** ERC-20 tokens can be integrated into various decentralized applications (dApps), allowing developers to build applications that utilize tokens for specific use cases, such as voting, rewards, governance, and more.
6. **Token Standards Evolution:** The success of ERC-20 paved the way for the development of other token standards, such as ERC-721 (non-fungible tokens) and ERC-1155 (multi-token standard), catering to different token use cases and enhancing the Ethereum ecosystem's versatility.

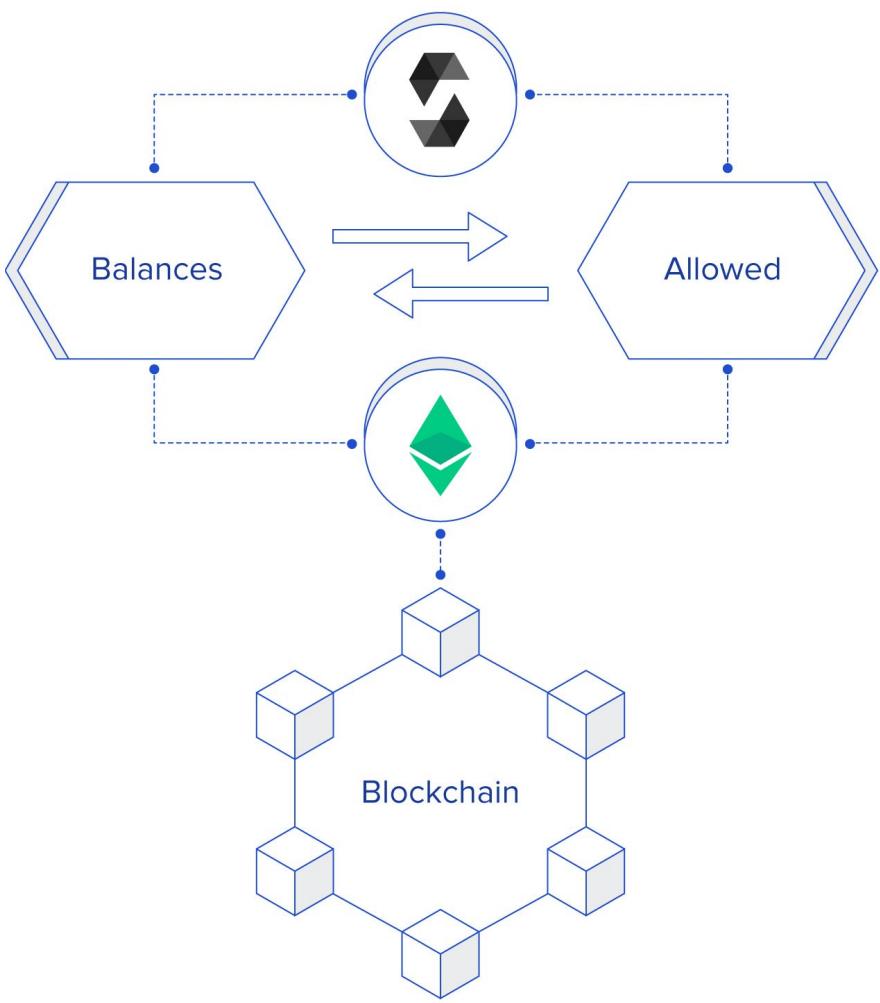

ERC20 Token - Disadvantages

- Limited Functionality:** ERC-20 tokens are primarily suited for fungible assets. If a project requires more complex features, such as non-fungible tokens (NFTs) or unique attributes for each token, ERC-20 might not be the ideal choice.
- Scalability and Gas Fees:** The Ethereum blockchain has faced scalability challenges, leading to network congestion and high gas fees during periods of heavy usage. This can impact the cost and speed of transactions involving ERC-20 tokens.
- Lack of Native Support for Advanced Features:** ERC-20 tokens lack built-in support for certain features, such as royalties, more intricate tokenomics, and on-chain interactions that other token standards might offer.
- Security Risks:** Although the ERC-20 standard provides a framework for secure token development, improper coding practices or vulnerabilities can still expose tokens to potential security risks and vulnerabilities.
- Lost Tokens:** ERC-20 tokens can be accidentally sent to the wrong addresses or lost due to mistakes in handling private keys. Unlike centralized systems, there's no straightforward way to recover lost tokens.
- Regulatory Concerns:** Due to the ease of creating tokens using the ERC-20 standard, there have been instances of fraudulent token sales or scams. This has led to regulatory scrutiny in some cases.

Writing an ERC20 Token in Solidity

ERC 721 Token

- An ERC-721 token is a **type of non-fungible token (NFT) standard** on the Ethereum blockchain.
- ERC-721 tokens are **unique and distinct from each other**.
- Each ERC-721 token has **individual properties, attributes, or characteristics**, making them ideal for representing ownership of one-of-a-kind digital or physical assets.
- The term "ERC-721" stands for "**Ethereum Request for Comment 721**," and
- it refers to the **standard that defines the rules and functions for creating and managing non-fungible tokens on the Ethereum platform**.
- This standard was introduced **to enable the creation of digital assets that can represent collectibles, virtual items, artwork, real estate, in-game items, and more**, where each token holds unique value.

ERC 721 Token Characteristics

1. Uniqueness:

- Each ERC-721 token has a distinct identifier, and no two tokens are the same. This allows for the representation of rare or unique items that hold individual value.

2. Properties and Metadata:

- ERC-721 tokens can include metadata, attributes, and additional information that provide context and value to the token. For example, a digital artwork NFT could include the artist's name, creation date, and other relevant details.

3. Ownership and Transfers:

- Ownership of an ERC-721 token is recorded on the blockchain. Tokens can be transferred between addresses using the standard transferFrom function. Ownership changes are transparent and verifiable on the blockchain.

4. Use Cases:

- ERC-721 tokens have a wide range of use cases, including digital art ownership, virtual collectibles, unique in-game items, domain names, real estate representation, identity verification, and more.

ERC 721 Token Characteristics

5. Standard Interfaces:

- ERC-721 defines a set of standard functions for interacting with tokens, including querying ownership, transferring ownership, and querying token metadata.

6. Decentralized Applications (dApps):

- Developers can build decentralized applications that utilize ERC-721 tokens. These dApps can create marketplaces, games, platforms for trading collectibles, and other innovative services that leverage the uniqueness of NFTs.

7. Ecosystem Growth:

- The popularity of ERC-721 tokens has led to the growth of NFT marketplaces and platforms, where users can buy, sell, and trade NFTs. These tokens have gained significant attention, especially in the realms of art, entertainment, and gaming.

8. Gas Costs and Scalability:

- Transacting with ERC-721 tokens can be more gas-intensive than ERC-20 tokens due to the uniqueness and additional metadata associated with each token. Scalability remains a consideration, especially during periods of high network congestion.

Comparison between ERC20 & ERC721

| Criteria | ERC-20 | ERC-721 |
|----------------------------|--|--|
| Fungibility | Fungible in nature. | Non-fungible in nature. |
| Token Identity | There is no specific disparity among the different tokens. | Each token has a specific identity and could be easily distinguished. |
| Collecting Tokens | ERC-20 tokens are not collectible. | You can collect ERC-721 tokens like fiat currency. |
| Value Fluctuation | The value of ERC-20 tokens remains the same. | The value of ERC-721 tokens fluctuates according to rarity and uniqueness. |
| Adoption | Commonly adopted. | Limited levels of acceptance. |
| Substitutes | Easier for substitution. | No scope for substitution. |
| Divisibility | Can be divisible into decimals. | ERC-721 tokens are not divisible. |
| Ownership Functions | No special ownership functions are allocated. | ERC-721 tokens can enable special ownership functions. |

Comparison between ERC20 & ERC721

| Aspect | ERC-20 Tokens | ERC-721 Tokens |
|---------------|---|---|
| Type | Fungible tokens (identical and interchangeable) | Non-fungible tokens (unique and distinct) |
| Individuality | Tokens are identical, no unique attributes | Each token has unique attributes or properties |
| Use Cases | Currency, utility tokens, rewards, ICOs | Digital collectibles, gaming items, unique assets |
| Transfers | Can be transferred on a one-to-one basis | Transfers may involve individual token properties |
| Standard | Single standard (ERC-20) | Single standard (ERC-721) |
| Functions | Basic functions: transfer, balanceOf, approve, etc. | Advanced functions for managing unique tokens |
| Properties | No inherent properties or metadata | Tokens can have metadata, name, and attributes |

Comparison between ERC20 & ERC721

| Aspect | ERC-20 Tokens | ERC-721 Tokens |
|-------------------|--|---|
| Interoperability | High interoperability across platforms | May require specialized interfaces for certain apps |
| Token Identifiers | Token IDs are not unique across contracts | Token IDs are unique within a contract |
| Example | Ethereum (ETH), Chainlink (LINK) | CryptoKitties, Decentraland LAND |
| Scalability | Scalable for large quantities of tokens | Potentially less scalable due to unique properties |
| Gas Costs | Lower gas costs due to standardized operations | Higher gas costs for more complex transfers |
| Complexity | Simpler to implement | More complex due to individual token attributes |
| Registries | Not required; tokens can exist independently | Often use token registries for unique IDs |

7. Security Aspects of Blockchain

Blockchain ensures trust in decentralized systems

- Provides immutability, transparency, and cryptographic security
- However, it is not immune to attacks and vulnerabilities

Core Security Features of Blockchain

- Cryptographic Hash Functions
- Public-Key Cryptography
- Consensus Mechanisms (PoW, PoS)
- Decentralization & Distributed Ledger

7. Security Aspects of Blockchain

51% Attack

- Occurs when a single entity controls majority of network hash power
- Can lead to double spending
- Threat mostly to smaller blockchain networks

Double Spending Attack

- Spending the same cryptocurrency twice
- Exploits transaction confirmation delays
- Mitigated by waiting for multiple confirmations

Sybil Attack

- Attacker creates multiple fake identities
 - Attempts to influence consensus
 - Mitigated using Proof-of-Work / Proof-of-Stake

7. Security Aspects of Blockchain

Smart Contract Vulnerabilities

- Reentrancy attacks
 - Integer overflow/underflow
 - Poor access control
 - Example: Exploitation of vulnerable contract logic

Private Key & Phishing Attacks

- Users targeted to reveal private keys
 - Wallet malware attacks
 - Irreversible loss of digital assets

Network-Level Attacks

- Eclipse attacks
 - Routing attacks (BGP hijacking)
 - Denial of Service (DoS)

7. Security Aspects of Blockchain

Key Security Challenges

- Scalability vs Security trade-off
 - Energy consumption (PoW)
 - Regulatory uncertainty
 - Smart contract audit complexity

Best Practices for Blockchain Security

- Use hardware wallets
 - Enable two-factor authentication (2FA)
 - Regular code audits
 - Network monitoring and anomaly detection

Mitigation Techniques

- Decentralized and robust consensus mechanisms
 - Smart contract audits and formal verification
 - Multi-signature wallets
 - Cold storage for private keys
 - Regular security testing
